

### **Rochester Electronics Manufactured Components**

Rochester branded components are manufactured using either die/wafers purchased from the original suppliers or Rochester wafers recreated from the original IP. All recreations are done with the approval of the OCM.

Parts are tested using original factory test programs or Rochester developed test solutions to guarantee product meets or exceed the OCM data sheet.

### **Quality Overview**

- ISO-9001
- AS9120 certification
- Qualified Manufacturers List (QML) MIL-PRF-35835
  - Class Q Military
  - Class V Space Level
- Qualified Suppliers List of Distributors (QSLD)

• Rochester is a critical supplier to DLA and meets all industry and DLA standards.

Rochester Electronics, LLC is committed to supplying products that satisfy customer expectations for quality and are equal to those originally supplied by industry manufacturers.

The original manufacturer's datasheet accompanying this document reflects the performance and specifications of the Rochester manufactured version of this device. Rochester Electronics guarantees the performance of its semiconductor products to the original OEM specifications. 'Typical' values are for reference purposes only. Certain minimum or maximum ratings may be based on product characterization, design, simulation, or sample testing.

### intط 80186/80188 HIGH-INTEGRATION 16-BIT MICROPROCESSORS

- Integrated Feature Set
  - Enhanced 8086-2 CPU
  - Clock Generator
  - 2 Independent DMA Channels
  - Programmable Interrupt Controller
  - 3 Programmable 16-bit Timers
  - Programmable Memory and
  - **Peripheral Chip-Select Logic** - Programmable Wait State Generator

  - Local Bus Controller
- Available in 10 MHz and 8 MHz Versions
- High-Performance Processor -4 Mbyte/Sec Bus Bandwidth Interface @ 8 MHz (80186)
  - 5 Mbyte/Sec Bus Bandwidth Interface @ 10 MHz (80186)

- Direct Addressing Capability to 1 Mbyte of Memory and 64 Kbyte I/O
- **Completely Object Code Compatible** with All Existing 8086, 8088 Software - 10 New Instruction Types
- Numerics Coprocessing Capability Through 8087 Interface
- Available in 68 Pin: - Plastic Leaded Chip Carrier (PLCC) - Ceramic Pin Grid Array (PGA)
  - Ceramic Leadless Chip Carrier (LCC)
- Available in EXPRESS - Standard Temperature with Burn-In - Extended Temperature Range
  - $(-40^{\circ}C \text{ to } + 85^{\circ}C)$

Table 1. Pin Descriptions

| Symbol  | Pin<br>No.           | Туре                | Name and Function  |  |
|---|----------------------|---------------------|--|--|
| V <sub>CC</sub>                                     | 9<br>43              | I                   | SYSTEM POWER: +5 volt power supply.  |  |
| V <sub>SS</sub>                                     | 26<br>60             | I                   | System Ground.   |  |
| RESET   | 57                   | 0                   | Reset Output indicates that the CPU is being reset, and can be used as a system reset. It is active HIGH, synchronized with the processor clock, and lasts an integer number of clock periods corresponding to the length of the RES signal.   |  |
| X1<br>X2  | 59<br>58             | і<br>О              | Crystal Inputs X1 and X2 provide external connections for a fundamental mode parallel resonant crystal for the internal oscillator. Instead of using a crystal, an external clock may be applied to X1 while minimizing stray capacitance on X2. The input or oscillator frequency is internally divided by two to generate the clock signal (CLKOUT).   |  |
| CLKOUT  | 56                   | 0                   | Clock Output provides the system with a 50% duty cycle waveform. All device pin timings are specified relative to CLKOUT.  |  |
| RES   | 24                   | I                   | An active $\overline{\text{RES}}$ causes the processor to immediately terminate its present activity, clear the internal logic, and enter a dormant state. This signal may be asynchronous to the processor clock. The processor begins fetching instructions approximately 6½ clock cycles after $\overline{\text{RES}}$ is returned HIGH. For proper initialization, $V_{CC}$ must be within specifications and the clock signal must be stable for more than 4 clocks with $\overline{\text{RES}}$ held LOW. $\overline{\text{RES}}$ is internally synchronized. This input is provided with a Schmitt-trigger to facilitate power-on $\overline{\text{RES}}$ generation via an RC network. |  |
| TEST  | 47                   | 1/0                 | $\overline{\text{TEST}}$ is examined by the WAIT instruction. If the $\overline{\text{TEST}}$ input is HIGH when<br>"WAIT" execution begins, instruction execution will suspend. $\overline{\text{TEST}}$ will be<br>resampled until it goes LOW, at which time execution will resume. If interrupts<br>are enabled while the processor is waiting for $\overline{\text{TEST}}$ , interrupts will be serviced.<br>During power-up, active $\overline{\text{RES}}$ is required to configure $\overline{\text{TEST}}$ as an input. This pin<br>is synchronized internally.   |  |
| TMR IN 0<br>TMR IN 1                                | 20<br>21             |                     | Timer Inputs are used either as clock or control signals, depending upon the programmed timer mode. These inputs are active HIGH (or LOW-to-HIGH transitions are counted) and internally synchronized.   |  |
| TMR OUT 0<br>TMR OUT 1                              | 22<br>23             | 0<br>0              | Timer outputs are used to provide single pulse or continous waveform generation, depending upon the timer mode selected.   |  |
| DRQ0<br>DRQ1  | 18<br>19             | l                   | DMA Request is asserted HIGH by an external device when it is ready for DMA<br>Channel 0 or 1 to perform a transfer. These signals are level-triggered and<br>internally synchronized.   |  |
| NMI   | 46                   | I                   | The Non-Maskable Interrupt input causes a Type 2 interrupt. An NMI transition from LOW to HIGH is latched and synchronized internally, and initiates the interrupt at the next instruction boundary. NMI must be asserted for at least one clock. The Non-Maskable Interrupt cannot be avoided by programming.   |  |
| INT0<br>INT1/SELECT<br>INT2/INTA0<br>INT3/INTA1/IRQ | 45<br>44<br>42<br>41 | <br> <br> /0<br> /0 | Maskable Interrupt Requests can be requested by activating one of these pins.<br>When configured as inputs, these pins are active HIGH. Interrupt Requests are<br>synchronized internally. INT2 and INT3 may be configured to provide active-<br>LOW interrupt-acknowledge output signals. All interrupt inputs may be<br>configured to be either edge- or level-triggered. To ensure recognition, all<br>interrupt requests must remain active until the interrupt is acknowledged. When<br>Slave Mode is selected, the function of these pins changes (see Interrupt<br>Controller section of this data sheet).  |  |

**NOTE:** Pin names in parentheses apply to the 80188.

|  | Table 1. Pin Descriptions (Continued)   |  |  |   |                                   |  |  |  |  |
|--|---|--|--|---|-----------------------------------|--|--|--|--|
| Symbol   | Pin<br>No.  | Туре   |  | Name and Function   |                                   |  |  |  |  |
| A19/S6<br>A18/S5<br>A17/S4<br>A16/S3   | 65<br>66<br>67<br>68  | 0<br>0<br>0<br>0   | significa<br>and T <sub>4</sub> ,<br>DMA-in  | Address Bus Outputs (16–19) and Bus Cycle Status (3–6) indicate the four most significant address bits during $T_1$ . These signals are active HIGH. During $T_2$ , $T_3$ , $T_W$ , and $T_4$ , the S6 pin is LOW to indicate a CPU-initiated bus cycle or HIGH to indicate a DMA-initiated bus cycle. During the same T-states, S3, S4, and S5 are always LOW. The status pins float during bus HOLD or RESET.   |                                   |  |  |  |  |
| AD15 (A15)<br>AD14 (A14)<br>AD13 (A13)<br>AD12 (A12)<br>AD11 (A11)<br>AD10 (A10)<br>AD9 (A9)<br>AD8 (A8)<br>AD7<br>AD6<br>AD5<br>AD4<br>AD3<br>AD2<br>AD1<br>AD0 | 1<br>3<br>7<br>10<br>12<br>14<br>16<br>2<br>4<br>6<br>8<br>11<br>13<br>15<br>17 | I/O<br>I/O<br>I/O<br>I/O<br>I/O<br>I/O<br>I/O<br>I/O<br>I/O<br>I/O | and dat<br>the low<br>to be tra  | Address/Data Bus signals constitute the time multiplexed memory or I/O address (T <sub>1</sub> )<br>and data (T <sub>2</sub> , T <sub>3</sub> , T <sub>W</sub> , and T <sub>4</sub> ) bus. The bus is active HIGH. A <sub>0</sub> is analogous to BHE for<br>the lower byte of the data bus, pins D <sub>7</sub> through D <sub>0</sub> . It is LOW during T <sub>1</sub> when a byte is<br>to be transferred onto the lower portion of the bus in memory or I/O operations. BHE<br>does not exist on the 80188, as the data bus is only 8 bits wide. |                                   |  |  |  |  |
| BHE/S7<br>(S7)   | 64  | 0  | During T <sub>1</sub> the Bus High Enable signal should be used to determine if data is to be<br>enabled onto the most significant half of the data bus; pins $D_{15}-D_8$ . BHE is LOW<br>during T <sub>1</sub> for read, write, and interrupt acknowledge cycles when a byte is to be<br>transferred on the higher half of the bus. The S <sub>7</sub> status information is available during<br>T <sub>2</sub> , T <sub>3</sub> , and T <sub>4</sub> . S <sub>7</sub> is logically equivalent to BHE. BHE/S7 floats during HOLD. On the<br>80188, S7 is high during normal operation. |   |                                   |  |  |  |  |
|  |   |  |  |   | BHE and A0 Encodings (80186 Only) |  |  |  |  |
|  |   |  | BHE<br>Value   | A0<br>Value   | Function                          |  |  |  |  |
|  |   |  | 0     0     Word Transfer       0     1     Byte Transfer on upper half of data bus (D15–D8)       1     0     Byte Transfer on lower half of data bus (D <sub>7</sub> –D <sub>0</sub> )       1     1     Reserved  |   |                                   |  |  |  |  |
| ALE/QS0  | 61  | 0  | Address Latch Enable/Queue Status 0 is provided by the processor to latch the address. ALE is active HIGH. Addresses are guaranteed to be valid on the trailing edge of ALE. The ALE rising edge is generated off the rising edge of the CLKOUT immediately preceding $T_1$ of the associated bus cycle, effectively one-half clock cycle earlier than in the 8086. The trailing edge is generated off the CLKOUT rising edge in $T_1$ as in the 8086. Note that ALE is never floated.   |   |                                   |  |  |  |  |
| WR/QS1   | 63  | 0  | Write Strobe/Queue Status 1 indicates that the data on the bus is to be written into a memory or an I/O device. WR is active for $T_2$ , $T_3$ , and $T_W$ of any write cycle. It is active LOW, and floats during HOLD. When the processor is in queue status mode, the ALE/QS0 and WR/QS1 pins provide information about processor/instruction queue interaction.  |   |                                   |  |  |  |  |
|  |   |  | QS1 QS0 Queue Operation  |   |                                   |  |  |  |  |
|  |   |  | 00No queue operation01First opcode byte fetched from the queue11Subsequent byte fetched from the queue10Empty the queue  |   |                                   |  |  |  |  |

# intel®

### Table 1. Pin Descriptions (Continued)

| Pin<br>No. | Туре                        | Name and Function   |  |  |  |  |  |  |
|------------|-----------------------------|---|--|--|--|--|--|--|
| 62         | 1/0                         | Read Strobe is an active LOW signal which indicates that the processor is performing a memory or I/O read cycle. It is guaranteed not to go LOW before the A/D bus is floated. An internal pull-up ensures that RD is HIGH during RESET. Following RESET the pin is sampled to determine whether the processor is to provide ALE, RD, and WR, or queue status information. To enable Queue Status Mode, RD must be connected to GND. RD will float during bus HOLD.   |  |  |  |  |  |  |
| 55         | I                           | spac<br>rising<br>fallin<br>Coni  | Asynchronous Ready informs the processor that the addressed memory<br>space or I/O device will complete a data transfer. The ARDY pin accepts a<br>rising edge that is asynchronous to CLKOUT, and is active HIGH. The<br>falling edge of ARDY must be synchronized to the processor clock.<br>Connecting ARDY HIGH will always assert the ready condition to the CPU.<br>If this line is unused, it should be tied LOW to yield control to the SRDY pin.  |  |  |  |  |  |
| 49         | I                           | spac<br>activ<br>relax<br>the c<br>signa<br>CPU   | Synchronous Ready informs the processor that the addressed memory space or I/O device will complete a data transfer. The SRDY pin accepts an active-HIGH input synchronized to CLKOUT. The use of SRDY allows a relaxed system timing over ARDY. This is accomplished by elimination of the one-half clock cycle required to internally synchronize the ARDY input signal. Connecting SRDY high will always assert the ready condition to the CPU. If this line is unused, it should be tied LOW to yield control to the ARDY in   |  |  |  |  |  |
| 48         | 0                           | LOCK output indicates that other system bus masters are not to gain<br>control of the system bus while LOCK is active LOW. The LOCK signal is<br>requested by the LOCK prefix instruction and is activated at the beginning<br>of the first data cycle associated with the instruction following the LOCK<br>prefix. It remains active until the completion of that instruction. No<br>instruction prefetching will occur while LOCK is asserted. When executing<br>more than one LOCK instruction, always make sure there are 6 bytes of<br>code between the end of the first LOCK instruction and the start of the<br>second LOCK instruction. LOCK is driven HIGH for one clock during RESET |  |  |  |  |  |  |
| 52         | 0                           |   |  |  | $\overline{S0} - \overline{S2}$ are encoded to provide bus-transaction   |  |  |  |
|            | -                           | infor   | matior   | 1:   |  |  |  |  |

### Table 1. Pin Descriptions (Continued)

| Symbol                               | Pin<br>No.                 | Туре             | Name and Function   |  |
|--------------------------------------|----------------------------|------------------|---|--|
| HOLD<br>HLDA                         | 50<br>51                   | I<br>O           | HOLD indicates that another bus master is requesting the local bus. The HOLD input is active HIGH. HOLD may be asynchronous with respect to the processor clock. The processor will issue a HLDA (HIGH) in response to a HOLD request at the end of $T_4$ or $T_i$ . Simultaneous with the issuance of HLDA, the processor will float the local bus and control lines. After HOLD is detected as being LOW, the processor will again drive the local bus and control lines. |  |
| UCS                                  | 34                         | 0                | Upper Memory Chip Select is an active LOW output whenever a memory reference is made to the defined upper portion (1K–256K block) of memory. This line is not floated during bus HOLD. The address range activating UCS is software programmable.   |  |
| LCS                                  | 33                         | 0                | Lower Memory Chip Select is active LOW whenever a memory reference is made to the defined lower portion $(1K-256K)$ of memory. This line is not floated during bus HOLD. The address range activating LCS is software programmable.   |  |
| MCS0<br>MCS1<br>MCS2<br>MCS3         | 38<br>37<br>36<br>35       | 0<br>0<br>0      | Mid-Range Memory Chip Select signals are active LOW when a memory reference is made to the defined mid-range portion of memory ( $8K-512K$ ). These lines are not floated during bus HOLD. The address ranges activating $MCSO-3$ are software programmable.  |  |
| PCS0<br>PCS1<br>PCS2<br>PCS3<br>PCS4 | 25<br>27<br>28<br>29<br>30 | 0<br>0<br>0<br>0 | Peripheral Chip Select signals $0-4$ are active LOW when a reference is made to the defined peripheral area (64 Kbyte I/O space). These lines are not floated during bus HOLD. The address ranges activating $\overline{PCS0}-4$ are software programmable.   |  |
| PCS5/A1                              | 31                         | 0                | Peripheral Chip Select 5 or Latched A1 may be programmed to provide a sixth peripheral chip select, or to provide an internally latched A1 signal. The address range activating PCS5 is software-programmable. PCS5/A1 does not float during bus HOLD. When programmed to provide latched A1, this pin will retain the previously latched value during HOLD.  |  |
| PCS6/A2                              | 32                         | 0                | Peripheral Chip Select 6 or Latched A2 may be programmed to provide a seventh peripheral chip select, or to provide an internally latched A2 signal. The address range activating PCS6 is software programmable. PCS6/A2 does not float during bus HOLD. When programmed to provide latched A2, this pin will retain the previously latched value during HOLD.  |  |
| DT/R                                 | 40                         | 0                | Data Transmit/Receive controls the direction of data flow through an external data bus transceiver. When LOW, data is transferred to the processsor. When HIGH, the processor places write data on the data bus.  |  |
| DEN                                  | 39                         | 0                | Data Enable is provided as a data bus transceiver <u>output</u> enable. $\overline{\text{DEN}}$ is active LOW during each memory and I/O access. $\overline{\text{DEN}}$ is HIGH whenever DT/R changes state. During RESET, $\overline{\text{DEN}}$ is driven HIGH for one clock, then floated. $\overline{\text{DEN}}$ also floats during HOLD.  |  |

**NOTE:** Pin names in parentheses apply to the 80188.

### FUNCTIONAL DESCRIPTION

### Introduction

The following Functional Description describes the base architecture of the 80186. The 80186 is a very high integration 16-bit microprocessor. It combines 15–20 of the most common microprocessor system components onto one chip while providing twice the performance of the standard 8086. The 80186 is object code compatible with the 8086/8088 microprocessors and adds 10 new instruction types to the 8086/8088 instruction set.

For more detailed information on the architecture, please refer to the 80C186XL/80C188XL User's Manual. The 80186 and the 80186XL devices are functionally and register compatible.

### **CLOCK GENERATOR**

The processor provides an on-chip clock generator for both internal and external clock generation. The clock generator features a crystal oscillator, a divideby-two counter, synchronous and asynchronous ready inputs, and reset circuitry.

### Oscillator

The oscillator circuit is designed to be used with a parallel resonant fundamental mode crystal. This is used as the time base for the processor. The crystal frequency selected will be double the CPU clock frequency. Use of an LC or RC circuit is not recommended with this oscillator. If an external oscillator is used, it can be connected directly to the input pin X1 in lieu of a crystal. The output of the oscillator is not directly available outside the processor. The recommended crystal configuration is shown in Figure 5.

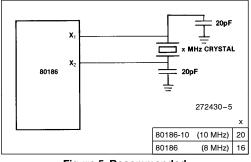

Figure 5. Recommended Crystal Configuration

#### 80186/80188

Intel recommends the following values for crystal selection parameters:

| Temperature Range:                             | 0 to 70°C      |
|--|----------------|
| ESR (Equivalent Series Resistance):            | $30\Omega$ max |
| C <sub>0</sub> (Shunt Capacitance of Crystal): | 7.0 pf max     |
| C <sub>1</sub> (Load Capacitance):             | 20 pf ± 2 pf   |
| Drive Level:                                   | 1 mW max       |

### **Clock Generator**

The clock generator provides the 50% duty cycle processor clock for the processor. It does this by dividing the oscillator output by 2 forming the symmetrical clock. If an external oscillator is used, the state of the clock generator will change on the falling edge of the oscillator signal. The CLKOUT pin provides the processor clock signal for use outside the device. This may be used to drive other system components. All timings are referenced to the output clock.

### **READY Synchronization**

The processor provides both synchronous and asynchronous ready inputs. In addition, the processor, as part of the integrated chip-select logic, has the capability to program WAIT states for memory and peripheral blocks.

### **RESET Logic**

The processor provides both a  $\overline{\text{RES}}$  input pin and a synchronized RESET output pin for use with other system components. The  $\overline{\text{RES}}$  input pin is provided with hysteresis in order to facilitate power-on Reset generation via an RC network. RESET output is guaranteed to remain active for at least five clocks given a  $\overline{\text{RES}}$  input of at least six clocks.

### LOCAL BUS CONTROLLER

The processor provides a local bus controller to generate the local bus control signals. In addition, it employs a HOLD/HLDA protocol for relinquishing the local bus to other bus masters. It also provides outputs that can be used to enable external buffers and to direct the flow of data on and off the local bus.

### **Memory/Peripheral Control**

The processor provides ALE,  $\overline{RD}$ , and  $\overline{WR}$  bus control signals. The  $\overline{RD}$  and  $\overline{WR}$  signals are used to strobe data from memory or I/O to the processor or to strobe data from the processor to memory or I/O. The ALE line provides a strobe to latch the address when it is valid. The local bus controller does not provide a memory/ $\overline{I/O}$  signal. If this is required, use the  $\overline{S2}$  signal (which will require external latching), make the memory and I/O spaces nonverlapping, or use only the integrated chip-select circuitry.

### **Local Bus Arbitration**

The processor uses a HOLD/HLDA system of local bus exchange. This provides an asynchronous bus exchange mechanism. This means multiple masters utilizing the same bus can operate at separate clock frequencies. The processor provides a single HOLD/HLDA pair through which all other bus masters may gain control of the local bus. External circuitry must arbitrate which external device will gain control of the bus when there is more than one alternate local bus master. When the processor relinquishes control of the local bus, it floats  $\overline{\text{DEN}}$ ,  $\overline{\text{RD}}$ ,  $\overline{\text{WR}}$ ,  $\overline{\text{SO}-\text{S2}}$ ,  $\overline{\text{LOCK}}$ , AD0–AD15 (AD0–AD7), A16–A19 (A8–A19), BHE (S7), and DT/R to allow another master to drive these lines directly.

### Local Bus Controller and Reset

During RESET the local bus controller will perform the following action:

 Drive DEN, RD, and WR HIGH for one clock cycle, then float.

#### NOTE:

RD is also provided with an internal pull-up device to prevent the processor from inadvertently entering Queue Status Mode during RESET.

- Drive SO-S2 to the inactive state (all HIGH) and then float.
- Drive LOCK HIGH and then float.
- Float AD0-15 (AD0-AD7), A16-19 (A8-A19), BHE (S7), DT/R.
- Drive ALE LOW (ALE is never floated).
- Drive HLDA LOW.

### PERIPHERAL ARCHITECTURE

All of the integrated peripherals are controlled by 16-bit registers contained within an internal 256-byte control block. The control block may be mapped into

# intel

either memory or I/O space. Internal logic will recognize control block addresses and respond to bus cycles. During bus cycles to internal registers, the bus controller will signal the operation externally (i.e., the RD, WR, status, address, data, etc., lines will be driven as in a normal bus cycle), but D<sub>15-0</sub> (D<sub>7-0</sub>), SRDY, and ARDY will be ignored. The base address of the control block must be on an even 256-byte boundary (i.e., the lower 8 bits of the base address are all zeros).

The control block base address is programmed by a 16-bit relocation register contained within the control block at offset FEH from the base address of the control block. It provides the upper 12 bits of the base address of the control block.

In addition to providing relocation information for the control block, the relocation register contains bits which place the interrupt controller into Slave Mode, and cause the CPU to interrupt upon encountering ESC instructions.

### **Chip-Select/Ready Generation Logic**

The processor contains logic which provides programmable chip-select generation for both memories and peripherals. In addition, it can be programmed to provide READY (or WAIT state) generation. It can also provide latched address bits A1 and A2. The chip-select lines are active for all memory and I/O cycles in their programmed areas, whether they be generated by the CPU or by the integrated DMA unit.

#### MEMORY CHIP SELECTS

The processor provides 6 memory chip select outputs for 3 address areas; upper memory, lower memory, and midrange memory. One each is provided for upper memory and lower memory, while four are provided for midrange memory.

#### UPPER MEMORY CS

The processor provides a chip select, called  $\overline{UCS}$ , for the top of memory. The top of memory is usually used as the system memory because after reset the processor begins executing at memory location FFFF0H.

### LOWER MEMORY CS

The processor provides a chip select for low memory called  $\overline{\text{LCS}}$ . The bottom of memory contains the interrupt vector table, starting at location 00000H.

The lower limit of memory defined by this chip select is always 0H, while the upper limit is programmable. By programming the upper limit, the size of the memory block is defined.

#### MID-RANGE MEMORY CS

The processor provides four  $\overline{\text{MCS}}$  lines which are active within a user-locatable memory block. This block can be located within the 1-Mbyte memory address space exclusive of the areas defined by  $\overline{\text{UCS}}$  and  $\overline{\text{LCS}}$ . Both the base address and size of this memory block are programmable.

### PERIPHERAL CHIP SELECTS

The processor can generate chip selects for up to seven peripheral devices. These chip selects are active for seven contiguous blocks of 128 bytes above a programmable base address. The base address may be located in either memory or I/O space. Seven CS lines called PCS0-6 are generated by the processor. PCS5 and PCS6 can also be programmed to provide latched address bits A1 and A2. If so programmed, they cannot be used as peripheral selects. These outputs can be connected directly to the A0 and A1 pins used for selecting internal registers of 8-bit peripheral chips.

#### **READY GENERATION LOGIC**

The processor can generate a READY signal internally for each of the memory or peripheral  $\overline{CS}$  lines. The number of WAIT states to be inserted for each peripheral or memory is programmable to provide 0–3 wait states for all accesses to the area for which the chip select is active. In addition, the processor may be programmed to either ignore external READY for each chip-select range individually or to factor external READY with the integrated ready generator.

### CHIP SELECT/READY LOGIC AND RESET

Upon RESET, the Chip-Select/Ready Logic will perform the following actions:

• All chip-select outputs will be driven HIGH.

- Upon leaving RESET, the UCS line will be programmed to provide chip selects to a 1K block with the accompanying READY control bits set at 011 to insert 3 wait states in conjunction with external READY (i.e., UMCS resets to FFFBH).
  - No other chip select or READY control registers have any predefined values after RESET. They will not become active until the CPU accesses their control registers. Both the PACS and MPCS registers must be accessed before the PCS lines will become active.

### **DMA Channels**

The DMA controller provides two independent DMA channels. Data transfers can occur between memory and I/O spaces (e.g., Memory to I/O) or within the same space (e.g., Memory to Memory or I/O to I/O). Data can be transferred either in bytes or in words (80186 only) to or from even or odd addresses. Each DMA channel maintains both a 20-bit source and destination pointer which can be optionally incremented or decremented after each data transfer (by one or two depending on byte or word transfers). Each data transfer consumes 2 bus cycles (a minimum of 8 clocks), one cycle to fetch data and the other to store data. This provides a maximum data transfer rate of 1.25 Mword/sec or 2.5 Mbytes/sec at 10 MHz (half of this rate for the 80188).

### DMA CHANNELS AND RESET

Upon RESET, the DMA channels will perform the following actions:

- The Start/Stop bit for each channel will be reset to STOP.
- · Any transfer in progress is aborted.

### Timers

The processor provides three internal 16-bit programmable timers. Two of these are highly flexible and are connected to four external pins (2 per timer). They can be used to count external events, time external events, generate nonrepetitive waveforms, etc. The third timer is not connected to any external pins, and is useful for real-time coding and time delay applications. In addition, the third timer can be used as a prescaler to the other two, or as a DMA request source.

## intel®

#### TIMERS AND RESET

Upon RESET, the Timers will perform the following actions:

- All EN (Enable) bits are reset preventing timer counting.
- For Timers 0 and 1, the RIU bits are reset to zero and the ALT bits are set to one. This results in the Timer Out pins going high.

### Interrupt Controller

The processor can receive interrupts from a number of sources, both internal and external. The internal interrupt controller serves to merge these requests on a priority basis, for individual service by the CPU.

Internal interrupt sources (Timers and DMA channels) can be disabled by their own control registers or by mask bits within the interrupt controller. The interrupt controller has its own control register that sets the mode of operation for the controller.

### INTERRUPT CONTROLLER AND RESET

Upon RESET, the interrupt controller will perform the following actions:

- All SFNM bits reset to 0, implying Fully Nested Mode.
- All PR bits in the various control registers set to 1. This places all sources at lowest priority (level 111).
- All LTM bits reset to 0, resulting in edge-sense mode.
- All Interrupt Service bits reset to 0.
- All Interrupt Request bits reset to 0.
- All MSK (Interrupt Mask) bits set to 1 (mask).
- All C (Cascade) bits reset to 0 (non-Cascade).
- All PRM (Priority Mask) bits set to 1, implying no levels masked.
- Initialized to Master Mode.

### **EXPLANATION OF THE AC SYMBOLS**

Each timing symbol has from 5 to 7 characters. The first character is always a "T" (stands for time). The other characters, depending on their positions, stand for the name of a signal or the logical status of that signal. The following is a list of all the characters. ters and what they stand for.

- Address A:
- ARY: Asynchronous Ready Input
- Clock Output C:
- CK: Clock Input
- CS:
- Chip Select Control ( $DT/\overline{R}$ ,  $\overline{DEN}$ , ...) CT:
- D: Data Input
- DEN DE:
- Logic Level High H:

intal

18

- IN: Input (DRQ0, TIM0, ...)
- Logic Level Low or ALE L:
- O: Output QS:
- Queue Status (QS1, QS2) RD signal, RESET signal Status (S0, S1, S2)
- R: S:
- SRY: Synchronous Ready Input
- V: Valid W:
- WR Signal
- No Longer a Valid Logic Level X:
- Z: Float

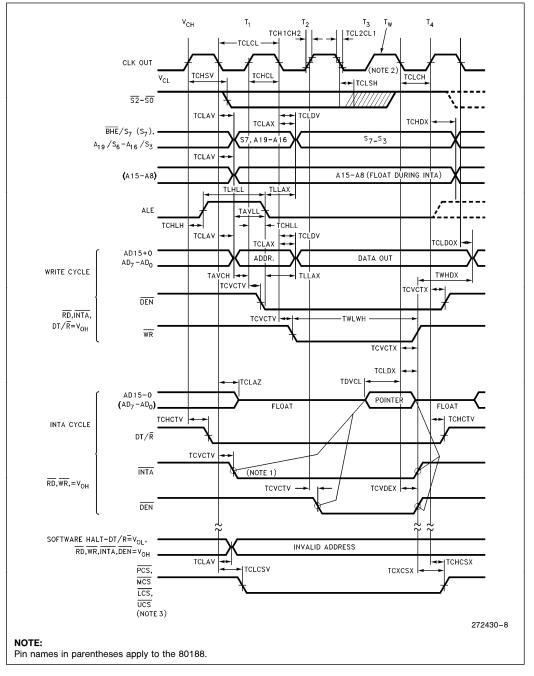

#### Examples:

- $T_{CLAV}$  Time from Clock low to Address valid  $T_{CHLH}$  Time from Clock high to ALE high  $T_{CLCSV}$  Time from Clock low to Chip Select valid

### **EXPRESS**

The Intel EXPRESS system offers enhancements to the operational specifications of the microprocessor. EXPRESS products are designed to meet the needs of those applications whose operating requirements exceed commercial standards.

The EXPRESS program includes the commercial standard temperature range with burn-in and an extended temperature range without burn-in.

With the commercial standard temperature range operational characteristics are guaranteed over the temperature range of 0°C to +70°C. With the extended temperature range option, operational characteristics are guaranteed over the range of -40°C to +85°C.

The optional burn-in is dynamic, for a minimum time of 160 hours at  $+125^\circ C$  with V<sub>CC</sub> = 5.5V  $\pm0.25 V,$  following guidelines in MIL-STD-883, Method 1015.

Package types and EXPRESS versions are identified by a one- or two-letter prefix to the part number. The prefixes are listed in Table 2. All A.C. and D.C. specifications not mentioned in this section are the same for both commercial and EXPRESS parts.

| Prefix | Package<br>Type | Temperature<br>Range | Burn-In |
|--------|-----------------|----------------------|---------|
| А      | PGA             | Commercial           | No      |
| Ν      | PLCC            | Commercial           | No      |
| R      | LCC             | Commercial           | No      |
| ТА     | PGA             | Extended             | No      |
| QA     | PGA             | Commercial           | Yes     |
| QR     | LCC             | Commercial           | Yes     |

#### NOTE:

Not all package/temperature range/speed combinations are available.

### **EXECUTION TIMINGS**

A determination of program execution timing must consider the bus cycles necessary to prefetch instructions as well as the number of execution unit cycles necessary to execute instructions. The following instruction timings represent the minimum execution time in clock cycles for each instruction. The timings given are based on the following assumptions:

- The opcode, along with any data or displacement required for execution of a particular instruction, has been prefetched and resides in the queue at the time it is needed.
- No wait states or bus HOLDS occur.
- All word-data is located on even-address boundaries.

All instructions which involve memory accesses can also require one or two additional clocks above the minimum timings shown due to the asynchronous handshake between the bus interface unit (BIU) and execution unit.

All jumps and calls include the time required to fetch the opcode of the next instruction at the destination address.

The 80186 has sufficient bus performance to ensure that an adequate number of prefetched bytes will reside in the queue (6 bytes) most of the time. Therefore, actual program execution time will not be substantially greater than that derived from adding the instruction timings shown.

The 80188 is noticeably limited in its performance relative to the execution unit. A sufficient number of prefetched bytes may not reside in the prefetch queue (4 bytes) much of the time. Therefore, actual program execution time may be substantially greater than that derived from adding the instruction timings shown.

### FOOTNOTES

reg is assigned according to the following:

| ES  |
|---|
|   |
| CS  |
| SS  |
| DS  |
| ng to the following tab                         |
| <b>8-Bit (w</b> = <b>0)</b><br>000 AL<br>001 CL |
| ٦   |

0

REG is assigned according to the following table:

| 16-Bit (w = 1) | 8-Bit (w = 0) |
|----------------|---------------|
| 000 AX         | 000 AL        |
| 001 CX         | 001 CL        |
| 010 DX         | 010 DL        |
| 011 BX         | 011 BL        |
| 100 SP         | 100 AH        |
| 101 BP         | 101 CH        |
| 110 SI         | 110 DH        |
| 111 DI         | 111 BH        |

The physical addresses of all operands addressed by the BP register are computed using the SS segment register. The physical addresses of the destination operands of the string primitive operations (those addressed by the DI register) are computed using the ES segment, which may not be overridden.
