

High-speed 1T 8051-based Flash MCU, 512 bytes SRAM, 16K bytes Flash, 128 bytes independent EEPROM, 12-bit ADC, Six 8-bit PWM Outputs, Three Timer/Counters, Two SSI, STOP current <1uA

## 1 GENERAL DESCRIPTION

The SC92F7423/7422/7421/7420 (hereinafter referred to as the SC92F742X) is a kind of enhanced high-speed 1T 8051-based industrial Flash Microcontroller unit (MCU), in which the instruction system is completely compatible with standard 8051 product series.

The SC92F742X is integrated with 16K bytes Flash ROM, 256 bytes+256 bytes SRAM, 128 bytes EEPROM, up to 26 General-purpose I/Os (GPIO), 14 IO external interrupters, three 16-bit timers, 11-channel 12-bit high-precision ADC, 6-channel independent 8-bit PWM, IO ports driven hierarchical control (P0 and P2 ports) with 4-level drive capability, internal  $\pm 1\%$  high-precision 16/8/4/1.33MHz high-frequency oscillator and 4% precision low-frequency 128 kHz oscillator, external crystal oscillator interface, two SSI communication interface and other resources. To improve the reliability and simplify the circuit design, the SC92F742X is also built in with 4-level optional LVR voltage, 2.4V ADC reference voltage and other high-reliability circuits.

The SC92F742X features excellent anti-interference performance, which make it possible to be widely applied to industrial control system, such as Internet of Things, intelligent home appliances, home automation, wireless communication, gaming peripherals and consumer applications.

## 2 FEATURES

Operating Voltage: 2.4V ~ 5.5V

Operating Temperature: -40 ~ 85°C

Package:

SC92F7423 (QFN28 / SOP28 / TSSOP28)  
SC92F7422 (QFN20 / SOP20 / TSSOP20)  
SC92F7421 (SOP16)  
SC92F7420 (SOP8)

Core: 1T 8051

Flash ROM: 16K bytes Flash ROM (MOVC) prohibited addressing 0000H ~ 00FFH) can be rewritten for 10,000 times

IAP: Code option into 0K, 0.5K, 1K or 16K

EEPROM: independent 128 bytes EEPROM can be

rewritten for 100000 times. The data written-in has more than 10-year preservation life.

SRAM: Internal 256 bytes + external 256 bytes

System Clock ( $f_{sys}$ ):

- Built-in high-frequency 16MHz oscillator ( $f_{HRC}$ )
- As the system clock source,  $f_{sys}$  can be set to 16MHz(2.9-5.5V), 8/4/1.33MHz (2.4-5.5V) by programmer selection.
- Frequency Error: Suitable for 2.9V ~ 5.5V and -20 ~ 85°C application environment, no more than  $\pm 1\%$  of frequency error

Built-in Low-Frequency Crystal Circuit

- Available to externally connect 32 KHz Oscillator, as the clock source of Base Timer, it can wake up stop mode

Built-in Low-Frequency 128 kHz Oscillator (LRC):

- Clock source of Base Timer (BTM), which can wake up the SC92F742X from stop mode
- Clock source of WatchDog (WDT)
- Frequency Error: 2.9V ~ 5.5V and -20 ~ 85°C application environment, no more than  $\pm 4\%$  of frequency error

Low-voltage Reset (LVR):

- 4-level LVR voltage options: 4.3V, 3.7V, 2.9V, 2.3V
- The default is the Code Option value selected by the user

Flash Programming and Emulation:

- 2-wire JTAG programming and emulation interface
- JTAG mode and Normal mode can be set through code option

Interruption (INT):

- 11 interrupt sources: Timer0, Timer1, Timer2, INT0 ~ 2, ADC, PWM, SSI0, SSI1 and Base Timer.

- 3 external interrupt vectors shared by 14 interrupt ports, all of which can be defined in rising-edge, falling-edge or dual-edge trigger mode.

- Two-level interrupt priority capability

**Digital Peripheral:**

- Up to 26 bidirectional independently controllable I/O interfaces, able to configure pull-high resistor independently
- P0/P2 ports with 4-level drive capability
- All I/Os equipped with sink current drive capability (75 mA)
- 11-bit WDT with optional clock division ratio
- 3 standard 80C51 Timer/Counters: Timer0, Timer1 and Timer2
- Timer2 can be configured as a Capture
- Six 8-bit PWM output channels with variable period and individual duty cycle,

- 5 I/Os as output of the 1/2-bias LCD COM
- 2 three-in-one serial communication interface: SSI0, SSI1

**Analog Peripheral:**

- 11-channel 12-bit  $\pm 2$ LSB ADC
  - Built-in 2.4V reference voltage
  - 2 options for ADC reference voltage:  $V_{DD}$  and internal 2.4V
  - Internal one-channel ADC, where  $V_{DD}$  can be measured directly
  - ADC conversion completion interrupt

**Power Saving Mode:**

- IDLE Mode: can be woken up by any interrupt.
- STOP Mode: current  $< 1\mu A$ , can be woken up by INT0 ~ 2 and Base Timer

## NAMING RULES FOR 92 SERIES PRODUCTS

Name	SC	92	F	7	4	2	3	X	M	28	U
S/R	①	②	③	④	⑤	⑥	⑦	⑧	⑨	⑩	⑪

S/R	Meaning
①	SinOne Chip abbreviation
②	Name of product series
③	Product Type (F: Flash MCU)
④	Serial Number: 7: GP Series, 8: TK series
⑤	ROM Size: 1 for 2K, 2 for 4K, 3 for 8K, 4 for 16K and 5 for 32K...
⑥	Subseries Number.: 0 ~ 9, A ~ Z
⑦	Number of Pins: 0: 8pin, 1: 16pin, 2: 20pin, 3: 28pin, 5: 32pin, 6: 44pin, 7: 48pin, 8: 64pin, 9: 100pin
⑧	Version Number: (default, B, C, D)
⑨	Package Type: (D: DIP; M: SOP; X: TSSOP; F: QFP; P: LQFP; Q: QFN; K: SKDIP)
⑩	Number of Pins.
⑪	Packaging Mode: (U: Tube; R: Tray; T: Reel)

## 4 INNER BLOCK DIAGRAM

The SC92F742X BLOCK DIAGRAM

## 5 FLASH ROM AND SRAM STRUCTURE

The structures of the SC92F742X's Flash ROM and SRAM are shown as follows:

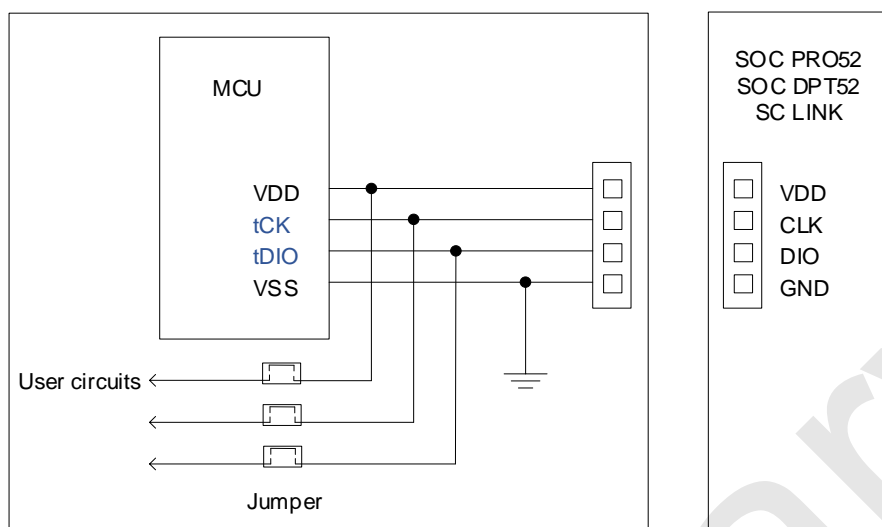

Flash ROM and SRAM Structure Diagram

### 5.1 flash rom

The SC92F742X provides 16K bytes of Flash ROM with the ROM address of 0000H ~ 3FFFH. These 16K bytes of Flash ROM can be rewritten 10,000 times, which is able to programming and erasing by specialized ICP programming device (SOC PRO52/DPT52/SC LINK) provided by SinOne. MOVC instruction is non-addressable within 256 bytes (address of 0000H ~ 00FFH).

EEPROM is an area separated from 16K bytes ROM with the address of 00H ~ 7FH, which can be accessed by single-byte reading and writing operations in the programme; for more details, refer to [17 EEPROM and IAP Operations](#).

The SC92F742X Flash ROM can be programmed by **tDIO**, **tCK**, VDD and VSS, with its specific connection shown as follows:

ICP Mode Flash Writer Programming Connection Diagram

**tDIO**, **tCK** are 2-wire JTAG programming and emulation interface, JTAG mode and Normal mode can be set through code option. The specific operation is as follows:

OP\_CTM1 (C2H@FFH) Customer Option Register1 (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	VREFS	-	-	DISJTG	IAPS[1:0]		-	-
R/W	R/W	-	-	R/W	R/W	R/W	-	-
POR	n	x	x	n	n	n	x	x

Bit Number	Bit Symbol	Description
4	DISJTG	JTAG mode switch 0 : JTAG mode enable 1 : Normal mode, JTAG function is invalid

## 5.2 CUSTOMER OPTION area (User Programming Setting)

A separate Flash area is embedded inside the SC92F742X, called Customer Option area, to save the user's presets. These presets will be written into IC when programming and loaded into SFR as default values during reset.

Option-related SFR Operating Instructions:

Reading and writing operations to option-related SFR are controlled by both register OPINX and register OPREG, with its respective address of Option SFR depending on register OPINX, as shown below:

Symbol	Address	Description	7	6	5	4	3	2	1	0	Initial value
OP_HRCR	83H@FFH	High-frequency RC oscillation frequency regulation	OP_HRCR[7: 0]								nnnnnnnnb
OP_CTM0	C1H@FFH	Customer Option Register 0	ENWD T	ENXTL	SCLKS[1: 0]		DISRS T	DISLV R	LVRS[1: 0]		nnnnnnnnb

OP_CTM1	C2H@FFH	Customer Option Register 1	VREF S	-	-	DISJT G	IAPS[1: 0]	-	-	nxnxxxxb
---------	---------	----------------------------	-----------	---	---	------------	------------	---	---	----------

OP\_HRCR (83H@FFH) System Clock Change Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	OP_HRCR[7: 0]							
R/W	R/W							
POR	n	n	n	n	n	n	n	n

Bit Number	Bit Symbol	Description
7 ~ 0	OP_HRCR[7: 0]	Internal high-frequency RC frequency adjustment  Central value 10000000b corresponds to HRC central frequency, the larger the value is, the faster the frequency will be, vice versa.

OP\_CTM0 (C1H@FFH) Customer Option Register0 (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	ENWDT	ENXTL	SCLKS[1: 0]		DISRST	DISLVR	LVRS[1: 0]	
R/W	R/W	R/W	R/W		R/W	R/W	R/W	
POR	n	n	n		n	n	n	

Bit Number	Bit Symbol	Description
7	ENWDT	WatchDog (WDT) control bit (This bit is transferred by the system to the value set by the user Code Option)  0: WDT invalid  1: WDT valid (WDT stops counting during IAP execution)

6	ENXTL	<p>External High-Frequency crystal oscillator selection bit</p> <p>0: External High-Frequency crystal Interface disable, P5.0 and P5.1 valid</p> <p>1: External High-Frequency crystal Interface enable, P5.0 and P5.1 invalid</p>
5 ~ 4	SCLKS[1: 0]	<p>System clock frequency selection bits</p> <p>00: Reserved;</p> <p>01: System clock frequency is HRC frequency divided by 2;</p> <p>10: System clock frequency is HRC frequency divided by 4;</p> <p>11: System clock frequency is HRC frequency divided by 12;</p>
3	DISRST	<p>IO/RST selection bit</p> <p>0: configure P1.1 as External Reset input pin</p> <p>1: configure P1.1 as GPIO</p>
2	DISLVR	<p>LVR control bit</p> <p>0: LVR valid</p> <p>1: LVR invalid</p>
1 ~ 0	LVR [1: 0]	<p>LVR voltage selection bits</p> <p>11: 4.3V reset</p> <p>10: 3.7 V reset</p> <p>01: 2.9V reset</p> <p>00: 2.3 V reset</p>

OP\_CTM1 (C2H@FFH) Customer Option Register1 (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	VREFS	-	-	DISJTG	IAPS[1: 0]		-	-
R/W	R/W	-	-	R/W	R/W	R/W	-	-
POR	n	x	x	n	n	n	x	x

Bit Number	Bit Mnemonic	Description
7	VREFS	Reference voltage selection bit (Initial values are configured by the user and loaded from Code Options)  0: Configure ADC VREF as $V_{DD}$ 1: Configure ADC VREF as internally correct 2.4V
4	DISJTG	JTAG mode switch 0 : JTAG mode enable 1 : Normal mode, JTAG function is invalid
3 ~ 2	IAPS[1: 0]	EEPROM and IAP Area Selection Bits  00: Code memory prohibits IAP operations, only EEPROM data memory is used for data storage  01: last 0.5k code memory allows IAP operation (3E00H ~ 3FFFH)  10: Last 1k code memory allows IAP operation (3C00H ~ 3FFFH)  11: All code memory allows IAP operation (0000H ~ 3FFFH)
6 ~ 5, 1 ~ 0	-	Reserved

### 5.2.1 OPTION-RELATED SFR OPERATING INSTRUCTIONS

Option-related SFR reading and writing operations are controlled by both OPINX and OPREG registers, with its respective position of Option SFR depending on OPINX and its value written to option-related SFR depending on register OPREG:

Symbol	Address	Description		POR
OPINX	FEH	Option Pointer	OPINX[7: 0]	00000000b
OPREG	FFH	Option Register	OPREG[7: 0]	nnnnnnnnb

When operating Option-related SFR, register OPINX stores the address of option-related registers and register OPREG stores corresponding value.

For example: To configure OP\_HRCR as 0x01, specific operation method is shown below:

C program example:

OPINX = 0x83;                   //Write OP\_HRCR address into OPINX register

OPREG = 0x01;                //Write 0x01 into OPREG register (the value to be written into OP\_HRCR register)

Assembler program example:

MOV OPINX, #83H           ;Write OP\_HRCR address into OPINX register

MOV OPREG, #01H           ;Write 0x01 into OPREG register (the value to be written into OP\_HRCR register)

Note: It is forbidden to write any value beyond SFR address of Customer Option region into OPINX register! Or else, it may cause abnormal system operation

## 5.3 SRAM

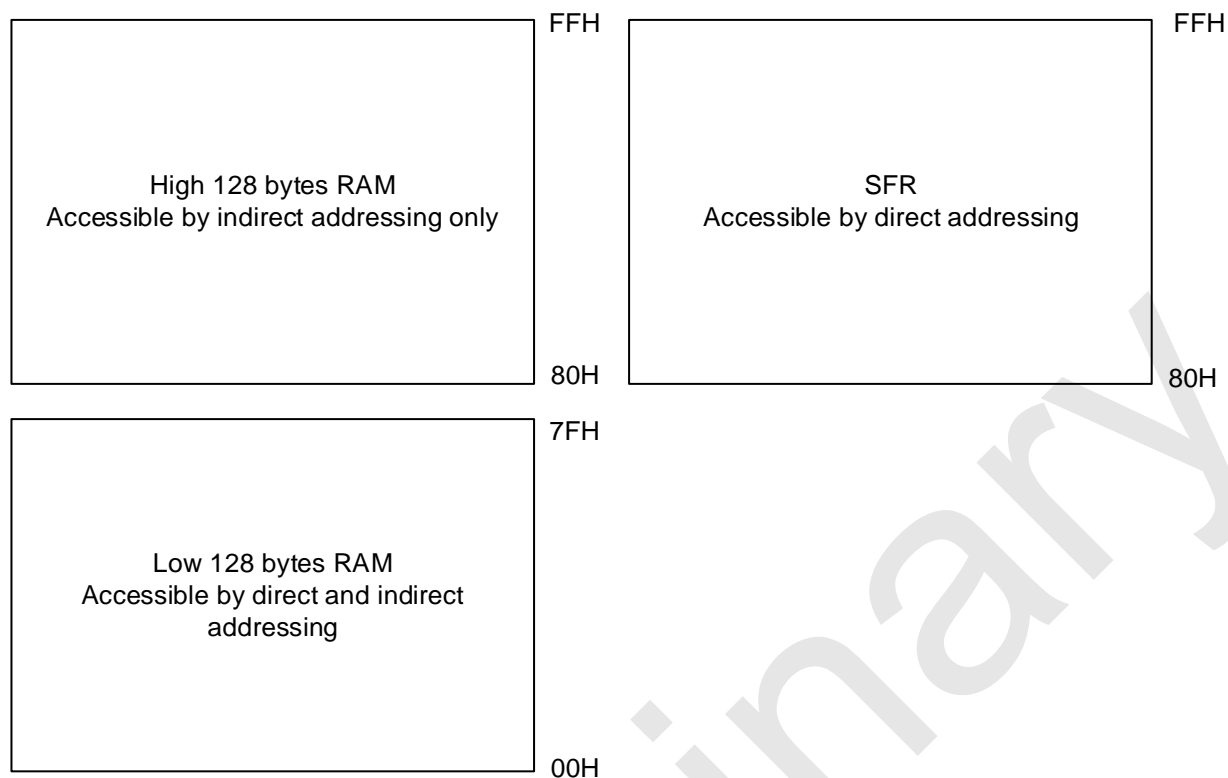

The SRAM of the SC92F742X Microcontroller Unit is divided into internal 256 bytes RAM and external 256 bytes RAM. The address of Internal RAM range from 00H to FFH, including high 128 bytes (address of from 80H to FFH) only addressed indirectly and low 128 bytes (address of from 00H to 7FH) addressed both directly and indirectly).

The address of special function register SFR is also from 80H to FFH. But the difference between SFR and internal high 128 bytes SRAM is that the former is addressed directly but the latter addressed indirectly only.

The address of External RAM from 0000H to 02FFH, which is addressed by MOVX instruction.

### 5.3.1 INTERNAL 256 BYTES SRAM

Internal low 128 bytes SRAM area is divided into three parts: ① Register bank 0 ~ 3, address from 00H to 1FH. The active bank is selected by bits RS1 and RS0 of PSW register. Using Register bank 0 ~ 3 can accelerate arithmetic speed; ② Bit addressing area, 20H ~ 2FH; user can use it as normal RAM or bitwise addressing RAM; for the latter, the bit address is from 00H to 7FH (bitwise addressing is different from normal SRAM byte-oriented addressing), which can be distinguished by instructions in programme; ③ User RAM and stack area, the 8-bit stack pointer will point to stack area after the SC92F742X reset; in general, users can set initial value in initializer, which is recommended to configure in the unit interval from E0H to FFH.

Internal 256 bytes RAM Structure Diagram

Internal low 128 bytes RAM structure is shown below:

SRAM Structure Diagram

### 5.3.2 EXTERNAL 256 BYTES SRAM

The external 256 bytes RAM (SRAM) can be accessed by instruction "MOVX A ,@Ri" or "MOVX @Ri, A" or instruction "MOVX A, @DPTR" or "MOVX @DPTR, A".

## 6 SPECIAL FUNCTION REGISTER (SFR)

### 6.1 SFR Mapping

The SC92F742X provides some registers equipped with special functions, called SFR. The address of such SFRs is from 80H to FFH, some are bit-addressable, and others are not. It is very convenient for these bit addressable registers to change the value of single bit, of which the address is end up with figure "0" or "8". All SFR shall use direct addressing for addressing.

The name and address of the SC92F742X special function registers are shown in the table below:

	0/8	1/9	2/A	3/B	4/C	5/D	6/E	7/F
F8h	-	-	-	-	CHKSUML	CHKSUMH	OPINX	OPREG
F0h	B	IAPKEY	IAPADL	IAPADH	IAPADE	IAPDAT	IAPCTL	-
E8h	-	-	-	-	-	-	-	OPERCON
E0h	ACC	-	-	-	-	-	-	-
D8h	P5	P5CON	P5PH	-	-	PWMDTY3	PWMDTY4	PWMDTY5
D0h	PSW	PWMCFG0	PWMCON	PWMPRD	PWMCFG1	PWMDTY0	PWMDTY1	PWMDTY2
C8h	T2CON	T2MOD	RCAP2L	RCAP2H	TL2	TH2	BTMCON	WDTCON
C0h	-	-	-	-	-	-	INT2F	INT2R
B8h	IP	IP1	INT0F	INT0R	INT1F	INT1R	-	-
B0h	-	-	-	-	-	-	-	-
A8h	IE	IE1	-	ADCCFG0	ADCCFG1	ADCCON	ADCVL	ADCVH
A0h	P2	P2CON	P2PH	-	SS0CON2	SS0CON0	SS0CON1	SS0DAT
98h	-	-	P0CON	P0PH	P0VO	SS1CON0	SS1CON1	SS1DAT
90h	P1	P1CON	P1PH	-	-	SS1CON2	-	IOHCON
88h	TCON	TMOD	TL0	TL1	TH0	TH1	TMCON	OTCON

80h	P0	SP	DPL	DPH	-	-	-	PCON
	Bit Addressable	Not Bit Addressable						

Notes:

- Hollow space of SFR refers to the fact that there is no such register RAM, it is not recommended for user to use.

## 6.2 SFR Instructions

For a description of each SFR, see the following table:

Register Name	Address	Description	7	6	5	4	3	2	1	0	Initial value
P0	80H	P0 Data Register	P07	P06	P05	P04	P03	P02	P01	P00	00000000b
SP	81H	Stack Pointer	SP[7: 0]								00000111b
DPL	82H	Data Pointer Low byte	DPL[7: 0]								00000000b
DPH	83H	Data Pointer High byte	DPH[7: 0]								00000000b
PCON	87H	Power Management Control Register	SMOD	-	-	-	-	-	STOP	IDL	0xxxxx00b

## 6.2.1 INTRODUCTION TO 8051 CPU CORE COMMONLY-USED SPECIAL FUNCTION REGISTERS

### Program Counter (PC)

PC does not belong to SFR. 16-bit PC is the register used to control instruction execution sequence. After power-on or reset of microcontroller unit, PC value is 0000H, that is to say, the microcontroller unit is to execute program from 0000H.

### Accumulator ACC (E0H)

Accumulator ACC is one of the commonly-used registers in 8051-based microcontroller unit, using A as mnemonic symbol in the instruction system. It is usually used to store operand and results for calculation or logical operations.

### B Register (F0H)

B Register shall be used together with Accumulator A in multiplication and division operations. For example, instruction "MUL A, B" is used to multiply 8-bit unsigned numbers of Accumulator A and Register B. As for the acquired 16-bit product, low byte is placed in A and High byte in B. As for "DIV A, B" is used to divide A by B, place integer quotient in A and remainder in B. Register B can also be used as common temporary register.

**Stack Pointer SP (81H)**

Stack pointer is an 8-bit specialized register, it indicates the address of top stack in common RAM. After resetting of microcontroller unit, the initial value of SP is 07H, and the stack will increase from 08H. 08H ~ 1FH is address of register banks 1 ~ 3.

**PSW (D0H) Program Status Word Register (Read/Write)**

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	CY	AC	F0	RS1	RS0	OV	F1	P
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
POR	0	0	0	0	0	0	0	0

Bit Number	Bit Symbol	Description									
7	CY	Carry Flag bit  1: The top digit of add operation has carry bit or the top digit of subtraction operation has the borrow digit  0: The top digit of add operation has no carry bit or the top digit of subtraction operation has no borrow digit									
6	AC	Carry-bit auxiliary flag bit (adjustable upon BCD code add and subtraction operations)  1: There is carry bit in bit 3 upon add operation and borrow bit in bit 3 upon subtraction operation  0: No borrow bit and carry bit									
5	F0	User flag bit									
4 ~ 3	RS1,RS0	Register banks selection bits  <table border="1"> <tr> <td>RS1</td><td>RS0</td><td>Current Selected Register banks 0 ~ 3</td></tr> <tr> <td>0</td><td>0</td><td>Group 0 (00H ~ 07H)</td></tr> <tr> <td>0</td><td>1</td><td>Group 1 (08H ~ 0FH)</td></tr> </table>	RS1	RS0	Current Selected Register banks 0 ~ 3	0	0	Group 0 (00H ~ 07H)	0	1	Group 1 (08H ~ 0FH)
RS1	RS0	Current Selected Register banks 0 ~ 3									
0	0	Group 0 (00H ~ 07H)									
0	1	Group 1 (08H ~ 0FH)									

		1	0	Group 2 (10H ~ 17H)
		1	1	Group 3 (18H ~ 1FH)
2	OV	Overflow flag bit		
1	F1	F1 flag bit User customized flag		
0	P	Parity flag bit. This flag bit is the parity value of the number of 1 in accumulator ACC.  1: Odd number of number of 1 in ACC 0: Even number of number of 1 in ACC (including 0)		

#### Data Pointer DPTR (82H, 83H)

The Data pointer DPTR is a 16-bit dedicated register, which is composed of Low byte DPL (82H) and High byte DPH (83H). DPTR is the only register in the traditional 8051-based MCU that can directly conduct 16-bit operation, which can also conduct operations on DPL and DPH by byte.

## 7 POWER, RESET AND CLOCK

### 7.1 Power Circuit

The SC92F742X Power includes circuits such as BG, LDO, POR and LVR, which are able to reliably work within the scope of 2.4V ~ 5.5V. Besides, a calibrated 2.4V voltage is built in the IC, which is used as ADC internal reference voltage. The user can search for specific configuration contents in [16 Analog-to-digital converter \(ADC\)](#).

### 7.2 Power-on Reset Process

After the SC92F742X power-on, the processes carried out before execution of client software are as follows:

- Reset stage
- Loading information stage
- Normal operation stage

#### 7.2.1 RESET STAGE

The SC92F742X will always be in reset mode. There will not be a valid clock until the voltage supplied to the SC92F742X is higher than certain voltage. The duration of reset stage is related to rising speed of external power. Once the external supply voltage is up to built-in POR voltage, the reset stage would be completed.

#### 7.2.2 LOADING INFORMATION STAGE

There is a preheating counter inside the SC92F742X. During the reset stage, this preheating counter is always

reset as zero. After the voltage is higher than POR voltage, internal RC oscillator starts to oscillate and this preheating counter starts to count. When internal preheating counter counts up to certain number, one byte data will be read from IFB of Flash ROM (including Code Option) for every certain number of HRC clock, which is saved to internal system registers. After the preheating is completed, such reset signal will end.

### 7.2.3 NORMAL OPERATING STAGE

After the loading information stage has been completed, the SC92F742X starts to read instruction code from Flash and enters normal operating stage. At this time, LVR voltage is the set value of Code Option written by user.

## 7.3 Reset Mode

The SC92F742X has 4 kinds of reset modes: ① External RST reset ② Low-voltage reset (LVR) ③ Power-on reset (POR) ④ WatchDog (WDT) reset.

### 7.3.1 EXTERNAL RST RESET

External reset is to supply a certain width reset pulse signal to the SC92F742X from the RST pin to realize the SC92F742X reset.

The RST/INT01/P1.1 can be used as RST (reset pin) when the SC92F742X power – on, the user can configure P1.1 as non-reset pin in Customer Option via PC programme software before programming.

### 7.3.2 LOW-VOLTAGE RESET LVR

The SC92F742X provides a low-voltage reset circuit. There are 4-level LVR voltage options: 4.3V, 3.7V, 2.9V and 2.3V. The default is the Option value written by user.

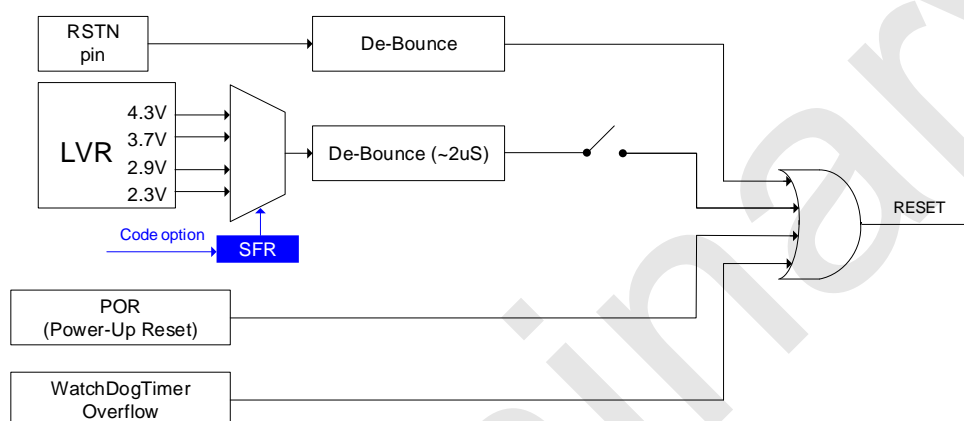

OP\_CTM0 (C1H@FFH) Customer Option Register 0 (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	ENWDT	ENXTL	SCLKS[1:0]		DISRST	DISLVR	LVRS[1:0]	
R/W	R/W	R/W	R/W		R/W	R/W	R/W	
POR	n	n	N		n	n	n	

Bit Number	Bit Symbol	Description
2	DISLVR	LVR control bit 0: LVR valid 1: LVR invalid
1 ~ 0	LVRS [1:0]	LVR voltage selection bits

		11: 4.3 V reset
		10: 3.7 V reset
		01: 2.9 V reset
		00: 2.3 V reset

The Circuit Diagram of the SC92F742X Resetting Part is shown below:

The SC92F742X Reset Circuit Diagram

### 7.3.3 POWER-ON RESET (POR)

The SC92F742X provides a power-on reset circuit. When power voltage  $V_{DD}$  is up to POR reset voltage, the system will be reset automatically.

### 7.3.4 WATCHDOG RESET (WDT)

The SC92F742X has a WDT, the clock source of which is the internal 128 kHz oscillator. User can select whether to enable WatchDog Reset function by programmer Code Option.

OP\_CTM0 (C1H@FFH) Customer Option Register 0 (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	ENWDT	ENXTL	SCLKS[1: 0]		DISRST	DISLVR	LVRS[1: 0]	
R/W	R/W	R/W	R/W		R/W	R/W	R/W	
POR	n	n	n		n	n	n	

Bit Number	Bit Symbol	Description
7	ENWDT	WDT control bit (This bit is transferred by the system to the value set by the user Code Option)  1: WDT valid  0: WDT invalid

WDTCON (CFH) WDT Control Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	-	-	-	CLRWDT	-	WDTCKS[2: 0]

001	250ms													
010	125ms													
011	62.5ms													
100	31.5ms													

		101	15.75ms	
		110	7.88ms	
		111	3.94ms	
7 ~ 5, 3	-	Reserved		

### 7.3.5 RESET INITIAL STATE

During reset, most registers are set to their initial values and the WDT remains disable. The initial value of stack pointer SP is 07h. Reset of “Hot Start” (such as WDT, LVR, etc.) will not influence SRAM which always keep the value before resetting. The SRAM contents will be retained until the power voltage is too low to keep RAM alive.

The initial value of power-on reset in SFRs is shown in the table below:

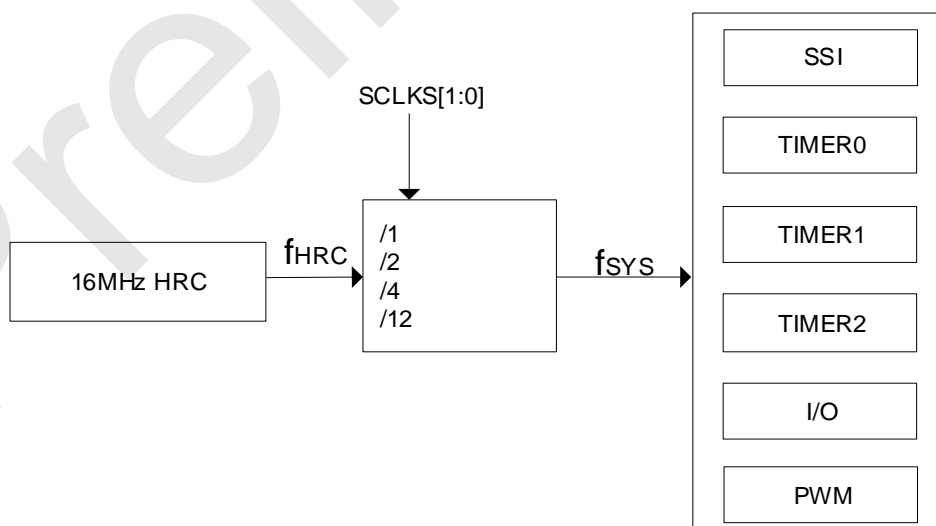

SFR Name	POR	SFR Name	POR

## 7.4 High-speed RC Oscillator Circuit

The SC92F742X has a built-in adjustable high-precision HRC. HRC is precisely calibrated to 16 MHz@5V/25°C when delivery. The user can set system clock as 16/8/4/1.33MHz by programmer Code Option. The calibration process is to filter the influence of processing deviation on precision. There will be certain drifting of this HRC depending on operating temperature and voltage. As for voltage drifting (2.9V ~ 5.5V) and temperature drifting (-20°C ~ 85°C), the deviation is within  $\pm 1\%$ .

The SC92F742X Internal Clock Relationship

OP\_CTM0 (C1H@FFH) Customer Option Register 0 (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Symbol	ENWDT	ENXTL	SCLKS[1: 0]		DISRST	DISLVR	LVRS[1: 0]	
R/W	R/W	R/W	R/W		R/W	R/W	R/W	
POR	n	n	n		n	n	n	

Bit Number	Bit Symbol	Description
5 ~ 4	SCLKS[1: 0]	System clock frequency selection bits: 00: reserved; System clock frequency is HRC frequency divided by 1, only valid when ENXTL=0; 01: system clock frequency is HRC frequency divided by 2; 10: system clock frequency is HRC frequency divided by 4; 11: system clock frequency is HRC frequency divided by 12;

The SC92F742X has a special function: the user can modify SFR value to adjust frequency of HRC within certain scope.

OP\_HRCR (83h@FFH) System Clock Change Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	OP_HRCR[7: 0]							
R/W	R/W							
POR	n	n	n	n	n	n	n	n

Bit Number	Bit Symbol	Description
7 ~ 0	OP_HRCR[7: 0]	HRC frequency change register

The value of OP\_HRCR[7:0] after power-on guarantee HRC is 16/8/4/1.33MHz (according to the user's choice of Code Option). There may be difference in OP\_HRCR[s] of each IC. The user can change the HRC operating frequency by modifying the value of this register.

When initial value is OP\_HRCR[s], IC system clock frequency  $f_{sys}$  can set specifically as 16/8/4/1.33MHz. For each change of 1 for OP\_HRCR [7: 0], the change of HRC frequency is about 0.23%@16MHz.

The relationship between OP\_HRCR [7: 0] and output frequency HRC is shown as follows:

OP_HRCR [7:0]	$f_{sys}$ actual output frequency (taking 16M as an example)
OP_HRCR [s]-n	$16000 \times (1 - 0.23\% \times n)$ kHz
...	....
OP_HRCR [s]-2	$16000 \times (1 - 0.23\% \times 2) = 15926.4$ kHz
OP_HRCR [s]-1	$16000 \times (1 - 0.23\% \times 1) = 15963.2$ kHz
OP_HRCR [s]	16000 kHz
OP_HRCR [s]+1	$16000 \times (1 + 0.23\% \times 1) = 16036.8$ kHz
OP_HRCR [s]+2	$16000 \times (1 + 0.23\% \times 2) = 16073.6$ kHz
...	...
OP_HRCR [s]+n	$16000 \times (1 + 0.23\% \times n)$ kHz

Note:

1. The value of OP\_HRCR[7:0] after each power-on of the IC is the value of high-frequency oscillator frequency  $f_{HRC}$  closest to 16MHz; the user can modify the value of HRC after each power-on by means of EEPROM to make IC system clock frequency  $f_{sys}$  work at the frequency the user needs.
2. To guarantee IC operating reliably, the maximum operating frequency of IC shall not exceed 16MHz;
3. The user shall confirm the change of HRC frequency will not

		influence other functions.
--	--	----------------------------

## 7.5 Low-speed RC Oscillator and Low-speed Clock Timer

The SC92F742X is equipped with a built-in 128 kHz RC oscillation circuit and a 32.768k Hz crystal oscillation circuit, which can be set as clock source of low-frequency clock timer Base Timer. This oscillator is directly connected to Base Timer, which can wake up CPU from STOP mode and generate interrupt.

BTMCON (CEH) Low-Frequency Timer Control Register (Read/Write)

Bit Number	Bit Symbol	Description
6	ENXTL	External 32KHz crystal option 0: External 32KHz crystal unenabled,P5.0, P5.1 valid and internal LRC invalid. 1: External 32KHz crystal enabled,P5.0, P5.1 invalid and internal LRC invalid.

The circuit diagram of the P5.0/P5.1 connect external 32KHz crystal as the Base Timer as follows:

32KHz external crystal connecting circuit diagram

The selection relation diagram of internal and external oscillations of the Base Timer is as follows:

Base Timer block

## 7.6 STOP Mode and IDLE Mode

The SC92F742X provides a SFR PCON, the user can configure bit 0 and bit 1 of this register to control MCU to enter different operating modes.

When PCON.1 = 1, internal high-frequency system clock would stop and system enter STOP mode, to save power. The system can be woken up from STOP by external interrupt INT0 ~ INT2, low-frequency clock interrupt, and external reset input.

When PCON.0 = 1, the programme would stop running and System enter IDLE mode. But the external equipment and clock will continue running, CPU will keep all states before entering IDLE mode. The system can be woken up from IDLE by any interrupt.

PCON (87H) Power Management Control Register (only for write, \*unreadable\*)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	SMOD	-	-	-	-	-	STOP	IDL
R/W	W	-	-	-	-	-	W	W
POR	0	x	x	x	x	x	0	0

Bit Number	Bit Symbol	Description
1	STOP	STOP mode control bit  0: normal operating mode  1: stop mode, high-frequency oscillator stops operating, low-frequency oscillator and WDT can select to work based on configuration

0	IDL	IDLE mode control bit  0: normal operating mode  1: IDLE mode, the program stops operating, but external equipment and clock continue to operate and all CPU states are saved before entering IDLE mode
---	-----	---

Notes: When Configure MCU to enter STOP or IDLE mode, the instruction of configuring PCON register should be followed by 8 “NOP” instructions rather than other instructions. Or else, it will be unable to execute following instructions normally after wake-up!

For example, configure MCU to enter STOP mode:

C program example:

```
#include"intrins.h"

PCON |= 0x02;           //Set to 1 for PCON bit1 STOP bit, configure MCU to enter STOP mode

_nop_ ();               //At least 8 _nop_ () required
_nop_ ();
_nop_ ();
_nop_ ();
_nop_ ();
_nop_ ();
_nop_ ();
_nop_ ();
_nop_ ();
.....
```

Assembly program example:

```
ORL PCON, #02H          ; Set to 1 for PCON bits1 STOP bit, configure MCU to enter STOP mode

NOP                     ; At least 8 NOP required
NOP
NOP
NOP
NOP
NOP
NOP
NOP
NOP
.....
```

## 8 CPU AND FUNCTION SYSTEM

### 8.1 CPU

CPU used by the SC92F742X is the high-speed 1T standard 8051 core, whose instructions are completely compatible with traditional 8051 core microcontroller unit.

### 8.2 Addressing Mode

The addressing mode of the SC92F742X 1T 8051 CPU instructions includes: ① Immediate Addressing ② Direct Addressing ③ Indirect Addressing ④ Register Addressing ⑤ Relative Addressing ⑥ Indexed Addressing ⑦ Bit Addressing

#### 8.2.1 IMMEDIATE ADDRESSING

Immediate addressing is also called immediate operand addressing, which is the operand given to participate in operation in instruction, the instruction is illustrated as follows:

MOV A, #50H (This instruction is to move immediate operand 50H to Accumulator A)

#### 8.2.2 DIRECT ADDRESSING

In direct addressing mode, the instruction operand field indicates the address to participate in operation operand. Direct addressing can only be used to address SFRs, internal data registers and bit address space. The SFRs and bit address space can only be accessed by direct addressing. For example:

ANL 50H, #91H (The instruction indicates the data in 50H unit AND immediate operand 91H, and the results are stored in 50H unit. 50H refers to direct address, indicating one unit in internal data register RAM.)

#### 8.2.3 INDIRECT ADDRESSING

Indirect addressing is expressed as adding "@" before R0 or R1. Suppose the data in R1 is 40H and the data of internal data register 40H unit is 55H, then the instruction will be

MOV A, @R1 (Move the data 55h to Accumulator A).

#### 8.2.4 REGISTER ADDRESSING

Register addressing is to operate the data in the selected registers R7 ~ R0, Accumulator A, general-purpose register B, address registers and carry bit C. The registers R7-R0 is indicated by lower 3 bits of instruction code. ACC, B, DPTR and carry bit C are implied in the instruction code. Therefore, register addressing can also include an implied addressing mode. The selection of register operating area depends on RS1 and RS0 of PSW. The registers indicated by instruction operand refers to the registers in current operating area.

INC R0 refers to (R0) +1 → R0

#### 8.2.5 RELATIVE ADDRESSING

Relative addressing is to add current value in program counter (PC) and the data in the second byte of the instruction, whose result shall be taken as the jump address of jump instruction. The Jump address is the target jump address, the current value in PC is the base address and the data in the second byte of the instruction is the offset address. Because the target jump address is relative to base address in PC, such addressing mode is called relative addressing. The offset is signed number, which ranges from +127 to -128, such addressing mode is mainly applied to jump instruction.

JC \$+50H

It indicates that if the carry bit C is 0, the contents in program counter PC remain the same, meaning no jump. On the contrary, if the carry bit C is 1, take the sum of the current value in PC and base address as well as offset 50H as the target jump address of this jump instruction.

## 8.2.6 INDEXED ADDRESSING

In indexed addressing mode, the instruction operand is to develop an indexed register to store indexed base address. Upon indexed addressing, the result by adding offset and indexed base address is taken as the address of operation operand. The indexed registers include PC and address register DPTR.

MOVC A, @A+DPTR

It indicates Accumulator A is used as offset register. Take the sum of the value in A and that in the address register DPTR as the address of operand. Then take the figure in the address out and transmit it to Accumulator A.

## 8.2.7 BITS ADDRESSING

Bit addressing is a kind of addressing mode when conducting bit operation on internal data storage RAM and SFRs which are able to carry out bit operations. Upon bit operations, by taking carry bit C as bit operation accumulator, the instruction operand will give the address of this bit directly, then execute bit operation based on the nature of operation code.

MOV C, 20H (Transmit the bit operation register with address of 20H into carry bit C)

# 9 INTERRUPT

The SC92F742X provides 11 interrupt sources: Timer0, Timer1, Timer2, INT0 ~ 2, ADC, PWM, SSI0, SSI1 and Base Timer. These 10 interrupt sources are equipped with 2-level interrupt priority-capability and each interrupt source can be individually configured in high priority or low priority. As for three external interrupts, the triggering condition of each interrupt source can be set as rising edge, falling edge or dual-edge trigger. Each interrupt is equipped with independent priority setting bit, interrupt flag, interrupt vector and enable bit. Global interrupt enable bit EA can enable or disable all interrupts.

## 9.1 Interrupt Source and Vector

Lists for the SC92F742X interrupt source, interrupt vector and related control bit are shown below:

Interrupt Source	Interrupt condition	Interrupt Flag	Interrupt Enable Control	Interrupt Priority Control	Interrupt Vector	Query Priority	Interrupt Number (C51)	Flag Clear Mode	Capability of Waking up STOP
INT0	Compliant with External interrupt 0 conditions	IE0	EINT0	IPINT0	0003H	1 (high)	0	-	Yes
Timer0	Timer0 overflow	TF0	ET0	IPT0	000BH	2	1	H/W Auto	No
INT1	Compliant with External interrupt 1 conditions	-	EINT1	IPINT1	0013H	3	2	-	Yes

Timer1	Timer1 overflow	TF1	ET1	IPT1	001BH	4	3	H/W Auto	No
SSI0	Receiving or transmitting completed	SSIF0	ESSI0	IPSSI0	0023H	5	4	Must be cleared by user	No
Timer2	Timer2 overflow	TF2	ET2	IPT2	002BH	6	5	Must be cleared by user	No
ADC	ADC conversion completed	ADCIF	EADC	IPADC	0033H	7	6	Must be cleared by user	No
SSI1	Receiving or transmitting completed	SSIF1	ESSI1	IPSSI1	003BH	8	7	Must be cleared by user	No
PWM	PWM overflow	PWMIF	EPWM	IPPWM	0043H	9	8	H/W Auto	No
BTM	Base timer overflow	BTMIF	EBTM	IPBTM	004BH	10	9	H/W Auto	Yes
INT2	External interrupt 2 conditions compliant	-	EINT2	IPINT2	0053H	11	10	-	Yes

Under the circumstance where the master interrupt control bit EA and the respective interrupt control bit have been enable, the interrupt occurrence is shown below:

**Timer Interrupt:** Interrupt generates when Timer0 or Timer1 overflows and the interrupt flag TF0 or TF1 is set to "1". When the microcontroller unit responds to the timer interrupt, the interrupt flag TF0 or TF1 is reset automatically by hardware. Interrupt generates when Timer2 overflows and the interrupt flag TF2 is set to "1". Once Timer2 interrupt generates, the hardware would not automatically clear TF2 bit, which must be cleared by the user's software.

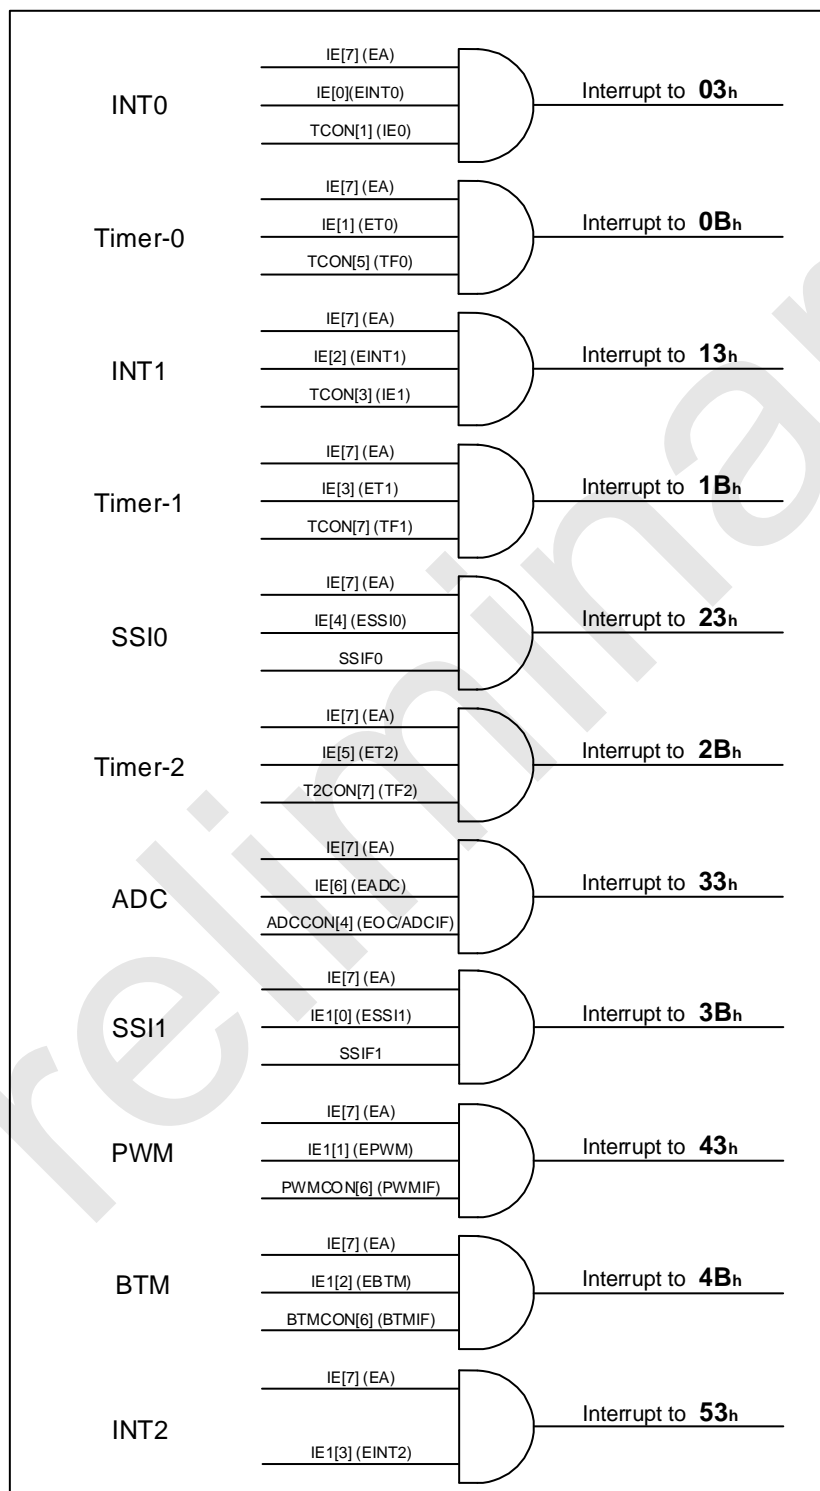

**ADC Interrupt:** After ADC conversion is completed, ADC interrupt generates, whose interrupt flag is the ADC conversion completion flag EOC/ADCIF (ADCCON.5). When user starts ADCS conversion, EOC will be reset automatically by hardware. Once conversion completes, EOC would be set to "1" automatically by hardware. User should clear the ADC interrupt flag by software when the interrupt service routine is executed after ADC interrupt generates.

**PWM Interrupt:** When PWM counter overflows (beyond PWMPD), The PWMIF bit will be set to 1 automatically by hardware, PWM interrupt generates. When the microcontroller unit executes PWM interrupt, the interrupt sign PWMIF will be clear to "0" automatically by hardware.

**External Interrupt INT0 ~ 2:** When any external interrupt pin meets the interrupt conditions, external interrupt generates. There are 4 external interrupt sources for INT0 and INT1 and 6 external interrupt sources for INT2, which can be set in rising edge, falling edge or dual edge interrupt trigger mode by setting SFRs (INTxF and INTxR). User can set the priority level of each interrupt through IP register. Besides, external interrupt INT0 ~ 2 can also wake up STOP mode of microcontroller unit.

## 9.2 Interrupt Structure Diagram

The SC92F742X interrupt structure is shown in the figure below:

The SC92F742X Interrupt Structure and Vector

### 9.3 Interrupt Priority

The SC92F742X microcontroller unit has two-level interrupt priority capability. The interrupt requests of these interrupt sources can be programmed as high-priority interrupt or low-priority interrupt, which is to realize the nesting of two levels of interrupt service programs. One interrupt can be interrupted by a higher priority interrupt request when being responded to, which can not be interrupted by another interrupt request at the same priority level, until such response to the first-come interrupt ends up with the instruction "RETI". Exist the interrupt service routine and return to main program, the system would execute one more instruction before responding to new interrupt request.

That is to say:

- ① A lower priority interrupt can be interrupted by a higher priority interrupt request, but not vice verse;
- ② Any kind of interrupt being responded to can not be interrupted by another interrupt request at the same priority level.

Interrupt query sequence: As for the sequence of that the SC92F742X microcontroller unit responds to the same priority interrupts which occur in the meantime, the priority sequence of interrupt response shall be the same as the interrupt query number in C51, which is to preferentially respond to the interrupt with smaller query number then the interrupt with bigger query number.

### 9.4 Interrupt Processing Flow

When any interrupt generates and is responded by CPU, the operation of main program will be interrupted to carry out the following operations:

- ① Complete execution of instruction being currently executed;
- ② Push the PC value into stack for site protection;
- ③ Load Interrupt vector address into program counter (PC);
- ④ Carry out corresponding interrupt service program;
- ⑤ End Interrupt service program ends and execute RETI;
- ⑥ Pop PC value from stack and return to the program before responding to the interrupt.

During this process, the system will not immediately respond to other interrupts at the same priority level, but it will keep all interrupt requests having occurred and respond to new interrupt requests upon completing handling of the current interrupt.

### 9.5 Interrupt-related SFR Registers

IE (A8H) Interrupt Enable Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
------------	---	---	---	---	---	---	---	---

## 10 TIMER / EVENT COUNTER TIMER0 AND TIMER1

The SC92F742X has two 16-bit Timer/Counters, Timer0 (T0) and Timer1 (T1), with two operating modes: counter mode and timer mode. The operating modes selected by bit C/Tx in the SFR TMOD. T0 and T1 are essentially adding counters with different counting source. The source of timer generated from system clock or frequency division clock, but the source of counters is the input pulse to external pin. Only when TRx = 1, will T0 and T1 be enabled on for counting.

In counter mode, each input pulse on T0 and T1 pin of Timer/Counters will make the count value of T0 and T1 increase by 1 respectively.

In timer mode, users can select  $f_{SYS}/12$  or  $f_{SYS}$  ( $f_{SYS}$  is the system clock after frequency division) as counting source of T0 and T1 by configuring SFR TMCON.

Timer/Counter T0 has 4 operating modes, and Timer/Counter T1 has 3 operating modes (Mode 3 does not exist):

- ① Mode 0: 13-bit Timer/Counter mode
- ② Mode 1: 16-bit Timer/Counter mode
- ③ Mode 2: 8-bit automatic reload mode
- ④ Mode 3: Two 8-bit timers/counters mode

In above modes, modes 0, 1 and 2 of T0 and T1 are the same, and mode 3 is different.

### 10.1 T0 and T1-related Special function Registers

## 10.2 T0 Operating Mode

Timer0 can be configured in one of four operating modes by setting the bit pairs (M10, M00) in the TMOD register.

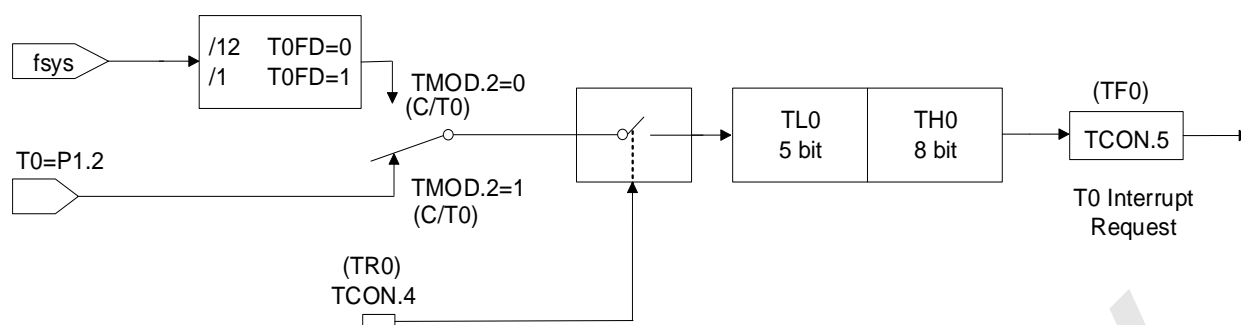

### Operating mode 0: 13-bit Timer/Counter

TH0 register is to store the high 8 bits (TH0.7 ~ TH0.0) of 13-bit Timer/Counter and TL0 is to store the low 5 bits (TL0.4 ~ TL0.0). The high three bits of TL0 (TL0.7 ~ TL0.5) are filled with uncertain values, they shall be omitted upon reading. When 13-bit Timer/Counter overflows with count increment, the system will set timer overflow flag TF0 to 1. An interrupt will be generated if the timer0 interrupt is enabled.

C/T0 bit selects the clock input source of Timer/Counter. If C/T0=1, the level fluctuation from high to low of Counter 0 input pin T0 will make Counter 0 data register add 1. If C/T0=0, the frequency division of system clock is the clock source of Timer0.

When TR0 = 1, Timer 0 is enabled. Setting TR0 would not reset the timer forcibly. It means that the timer register will start to count from the value of last clearing of TR0. Therefore, before enable the timer, it is required to configure the initial value of timer register.

When configured as a timer, the SFR T0FD is used to select fractional frequency ratio of clock source.

Operating mode 0: 13-bit Timer/Counter

### Operating Mode 1: 16 Counter/Timer

Except for using 16 bits of (valid for all 8 bits of TL0) Timer/Counter, in mode 1 and mode 0, the operating mode, opening and configuration method are the same.

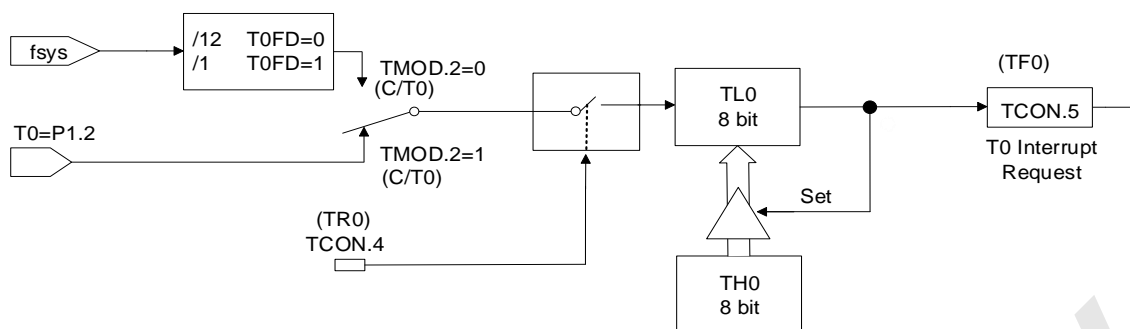

Operating mode 1: 16-bit Timer/Counter

### Operating Mode 2: 8 Automatic Reload Counter/Timer

In operating mode 2, Timer0 is 8-bit automatic reload Timer/Counter. TL0 is to store counting value and TH0 is to store the reload value. When the counter in TL0 overflows and turn to 0x00, the overflow flag of Timer TF0 will be set to 1, and the data in register TH0 will be reloaded into register TL0. If the timer interrupt enabled, setting TF0 to 1 will generate an interrupt, but the reloaded value in TH0 will remain the same. Before starting the Timer to count correctly, TL0 shall be initialized to the required value.

Except for automatic reloaded function, the enabling and configuration mode of Timer/Counter in operating mode 2 shall be the same as that in mode 0 and mode 1.

When configured as a timer, the SFR TMCON bit 0 (T0FD) is used to select fractional frequency ratio of system clock fsys.

Operating Mode 2: 8 Automatic Reload Counter/Timer

### Operating Mode 3: Two 8-bit Counter/Timer (only for Timer0)

In operating mode 3, Timer0 is used as two independent 8-bit Timer/Counters, respectively controlled by TL0 and TH0. TL0 is controlled by control bit (in TCON) and status bit (in TMOD) of Timer0 (TR0), C/T0, TF0. Timer0 is selected as Timer or Counter by TMOD bit 2 (C/T0).

TH0 is only limited to in Timer Mode, which is unable to configure as a Counter by TMOD.2 (C/T0). TH0 is enabled by set the timer control bit TR1 to 1. When overflow occurs and interrupt is discovered, set TF1 to 1 and proceed the interrupt as T1 interrupt.

When T0 is configured in Operating Mode 3, TH0 Timer occupies T1 interrupt resources and TCON register and the 16-bit counter of T1 will stop counting, equivalently "TR1=0". When adopting TH0 timer, it is required to configure TR1=1.

## 10.3 T1 Operating Mode

Timer1 can be configured in one of three operating modes by setting the bit pairs (M11, M01) in the TMOD register.

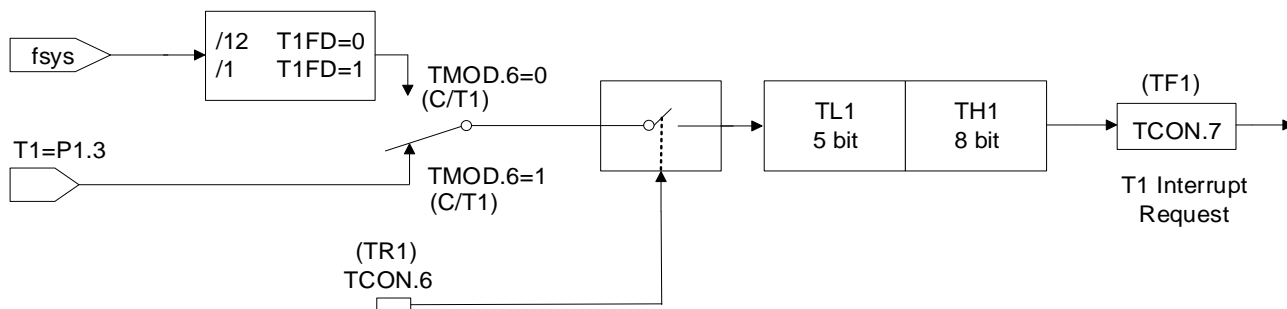

### Operating mode 0: 13-bit Timer/Counter

TH1 register is to store high 8-bit (TH1.7 ~ TH1.0) of 13-bit Timer/Counter and TL1 is to store low 5-bit (TL1.4 ~ TL1.0). The high 3-bit of TL1 (TL1.7 ~ TL1.5) are uncertain values, they shall be omitted upon reading. When 13-bit Timer/Counter overflow with count increment, the system will set timer overflow flag TF1 as 1. An interrupt will be generated if the timer1 interrupt is enabled. C/T1 bit selects the clock input source of Timer/Counter.

If C/T1=1, the level fluctuation from high to low of timer1 input pin T1 will make timer1 data register add 1. If C/T1=0, the frequency division of system clock is the clock source of timer1.

When TR1 is set to 1 and the timer is enabled. Setting TR1 does not force to reset timer counters, it means, if set TR1 to 1, the timer register will start to count from the value of last clearing of TR1. Therefore, before allowing timer, it is required to configure the initial value of timer register.

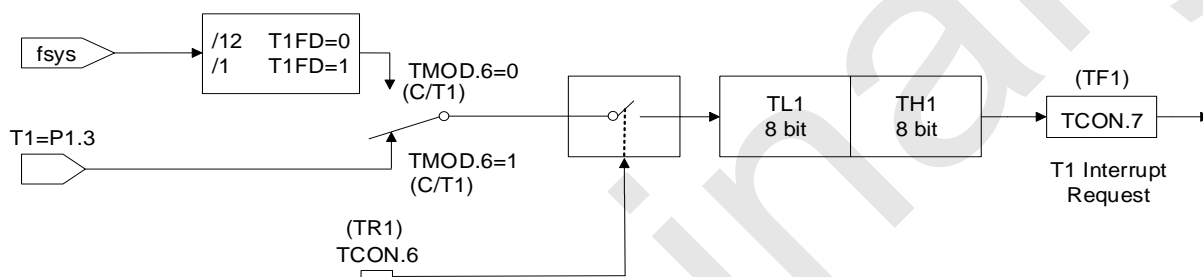

When configured as timer, the SFR T1FD is used to select fractional frequency ratio of clock source.

Operating mode 0: 13-bit Timer/Counter

### Operating Mode 1: 16 Counter/Timer

Except for using 16-bit (valid for 8-bit data of TL1) Timer/Counter, the operating mode of mode 1 and mode 0 is the same. And the opening and configuration mode of both are also the same.

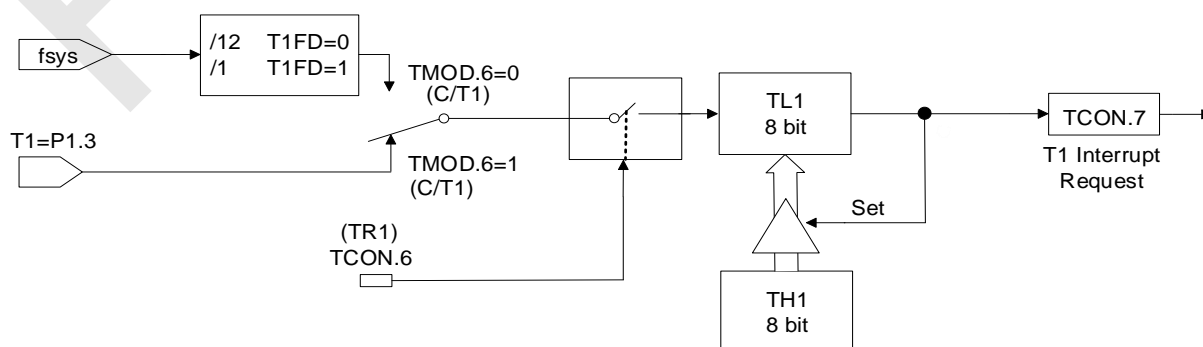

Operating mode 0: 16-bit Timer/Counter

### Operating Mode 2: 8 Automatic Reload Counter/Timer

In operating mode 2, Timer1 is 8-bit automatic reload Timer/Counter. TL1 is to store counting value and TH1 is to store the reload value. When the counter in TL1 overflows 0x00, the overflow flag of Timer TF1 will be set to 1, and the value of register TH1 will be reloaded into register TL1. If enable the timer interrupt, setting TF1 to 1 will generate an interrupt, but the reloaded value in TH1 will remain unchanged. Before allowing Timer to correctly count, TL1 shall be initialized to the required value.

Except for automatic reloaded function, the enabling and configuration mode of Timer/Counter in operating mode 2 shall be the same as that of mode 0 and mode 1.

When configured as timer, the SFR TMCON bit 4 (T1FD) is used to select the ratio of clock source of timer to fractional frequency of system clock  $f_{sys}$ .

Operating Mode 2: 8 Automatic Reload Counter/Timer

## 11 TIMER / EVENT COUNTER TIMER2

Timer2 inside the SC92F742X microcontroller unit has two operating modes, namely counter mode and timer mode. There is a control bit C/T2 in SFR T2CON to select Timer or Counter for T2. They are adding counters in nature, differing in counting source. The clock source of T2 comes from system clock or frequency division clock, but the source of counters is the input pulse to external pin. TR2 is the counting switch of Timer/Counter T2. Only when TR2 = 1, will T2 be enabled for counting.

In counter mode, each input pulse on T2 pin will make the counting value of T2 increase by 1.

In timer mode, users can select  $f_{sys}/12$  or  $f_{sys}$  as counting source of T2 by configuring SFR TMCON.

Timer/Counter T2 has 3 operating modes:

- ① Mode 0: 16-bit capture mode
- ② Mode 1: 16-bit automatic reload timer mode
- ③ Mode 3: Programmable clock output mode

## 11.2 T2 Operating Mode

The operating mode and configuration mode of Timer2 are shown in the table below:

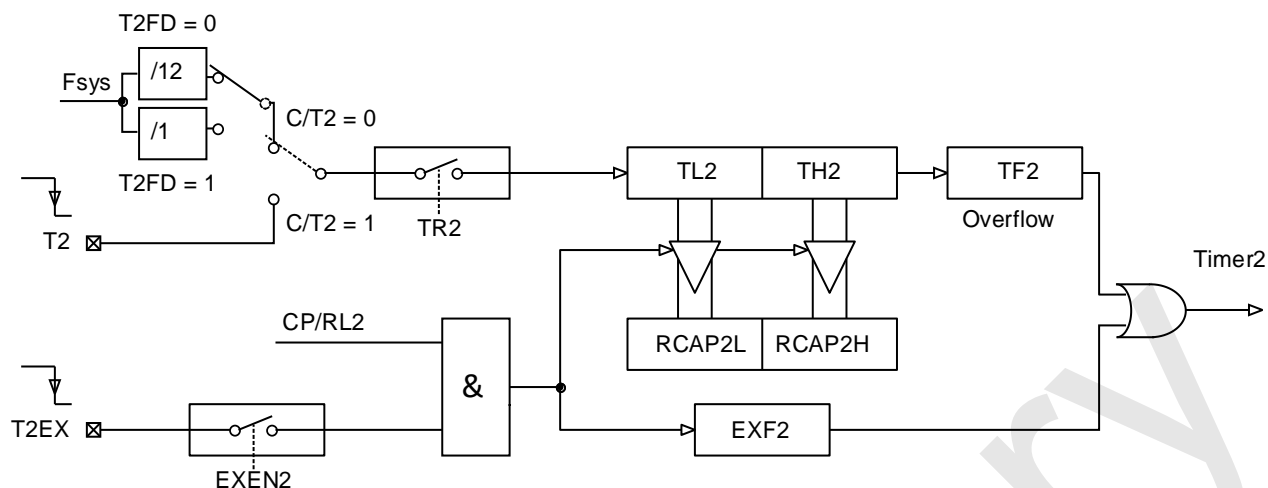

C/T2	T2OE	DCEN	TR2	CP/RL2	Mode	
X	0	X	1	1	0	16-bit capture
X	0	0	1	0	1	16-bit automatic reload timer
X	0	1	1	0		
0	1	X	1	X	3	Only used for programmable clock
					3	Programmable clock output with baud rate generator
X	X	X	0	X	X	Timer2 stops, but T2EX channel is also available
1	1	X	1	X		Not recommended

### Operating Mode 0: 16-bit capture

In capture mode, there are two options for EXEN2 bit in T2CON.

If EXEN2 = 0, Timer2 is taken as 16-bit timer or counter; if ET2 is set to 1, Timer2 will set up TF2 and generate an interrupt when Timer2 overflows.

If EXEN2=1, conduct the same operations as above on Timer2, the falling edge signal on external input T2EX can make current value in TH2 and TL2 captured into RCAP2H and RCAP2L. Besides, the falling edge signal on T2EX can also cause EXF2 in T2CON to be set to 1. If ET2 is set to 1, bit EXTF2, like TF2, will also trigger an interrupt.

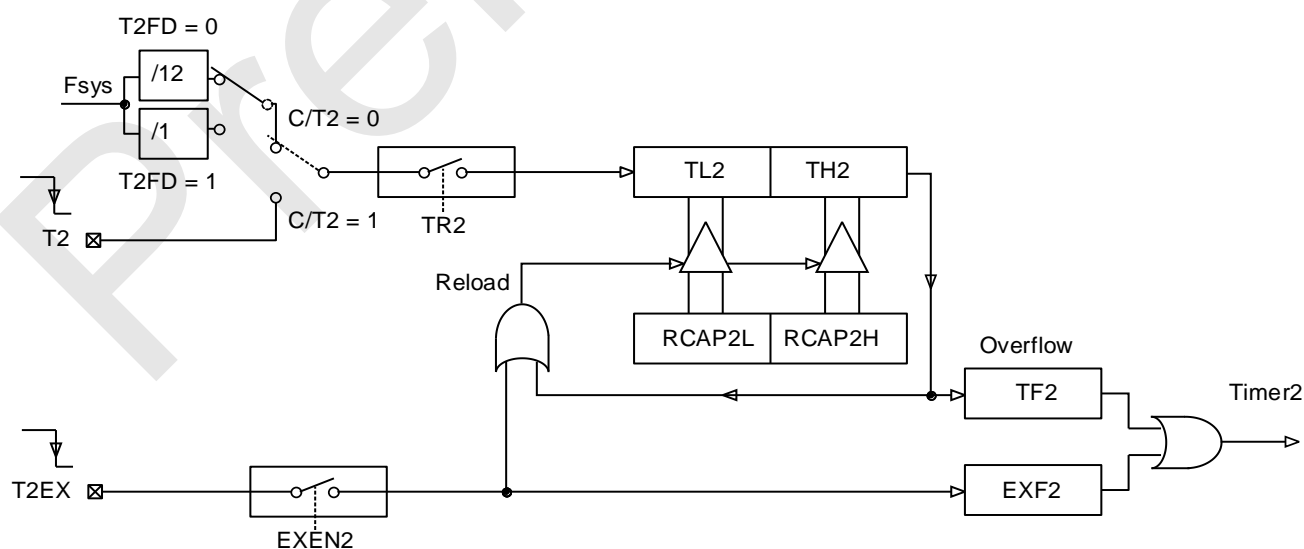

Operating Mode 0: 16-bit capture

### Operating Mode 1: 16-bit Automatic Reload Timer

In the 16-bit automatic reload mode, Timer2 can be selected to work in incrementing or decreasing counting mode. This function can be selected by DCEN bit in T2MOD (decreasing counting allowed). After system reset, the reset value of DCEN bit is 0 and Timer2 is defaulted as decreasing counting. When setting DCEN to 1, the incrementing or decreasing counting depends on the level of T2EX pin.

When DCEN = 0, There are two options for EXEN2 bit in T2CON:

1. EXEN=0, Timer2 will increase to 0xFFFFH and set TF2 bit after overflow. Meanwhile, the timer will load 16-bit value in registers RCAP2H and RCAP2L written by user software into registers TH2 and TL2 automatically.
2. EXEN2=1, both the overflow and the falling edge signal on external input T2EX can trigger a 16-bit count value reloading and set EXF2 bit. If T2 interrupt is enabled (ET2=1), both TF2 and EXF2 bit can generate an interrupt.

Operating Mode 1: 16-bit Automatic Reload Timer DCEN = 0

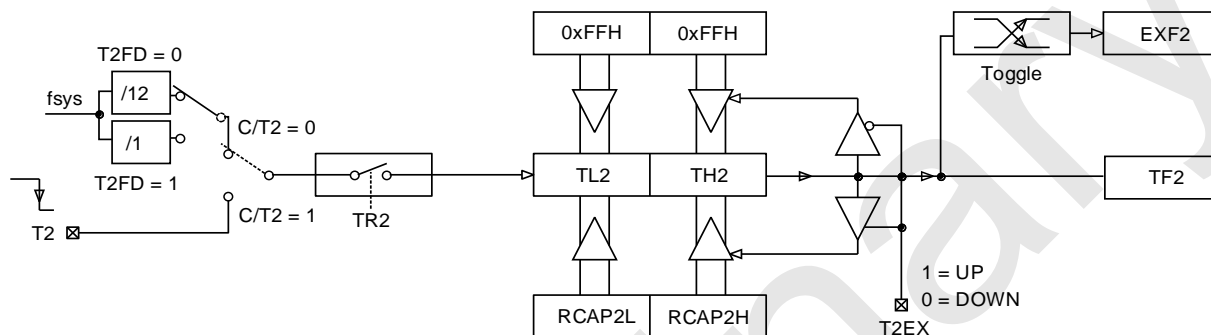

Configure DCEN bit to allow Timer2 for incremental or decreasing counting. When DCEN=1, T2EX pin controls

the count direction, and the control of EXEN2 becomes invalid.

Setting T2EX to 1 can conduct incremental count on Timer2. The Timer overflows when it increases to 0xFFFFH, then it sets TF2 bit. Besides, the overflow can also respectively cause 16-bit value in RCAP2H and RCAP2L to be reloaded into timer registers.

Setting T2EX to 0 can conduct decreasing count on Timer2. When the value in TH2 and TL2 is equal to that of RCAP2H and RCAP2L, the timer overflows. TF2 bit will be set up and 0xFFFFH reloaded into timer register.

No matter whether timer2 overflows or not, bit EXF2 will be used as the 17<sup>th</sup> bit of the results. Under such operating mode, EXF2 is no longer taken as interrupt flag.

Operating Mode 1: 16-bit Automatic Reload Timer DCEN = 1

### Operating Mode 3: Programmable Clock Output

In this mode, T2 can be programmed to output a 50% duty cycle clock: when  $C/\overline{T2} = 0$  and T2OE = 1, Timer2 is taken as clock generator

In this mode, duty cycle of T2 output clock is 50%

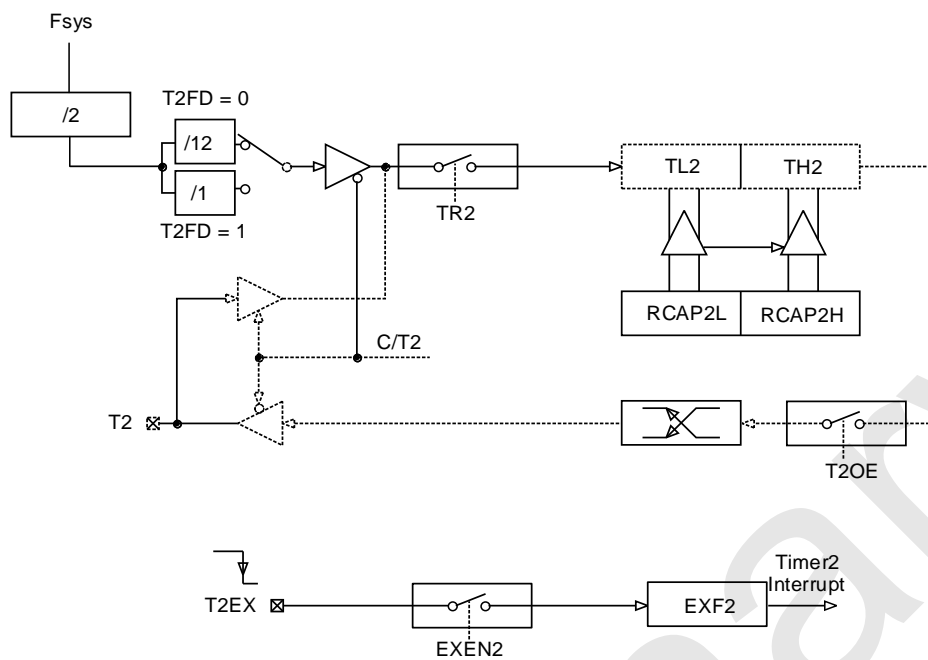

$$\text{Clock Out Frequency} = \frac{fn2}{(65536 - [RCAP2H, RCAP2L]) \times 4};$$

Including, fn2 is the clock frequency of Timer2

$$fn2 = \frac{fsys}{12}; \quad T2FD = 0$$

$$fn2 = fsys; \quad T2FD = 1$$

Overflow of Timer2 does not generate an interrupt, T2 pin is taken as clock output.

Operating Mode 3: Programmable Clock Output

Note:

1. Both TF2 and EXF2 can generate interrupt request of Timer2, both of which has the same interrupt vector;
2. TF2 and EXF2 can be set by software, only software and hardware reset can clear TF2 and EXF2;
3. When EA = 1 and ET2 = 1, setting up TF2 or EXF2 to 1 can arouse interrupt of Timer2;

## 12 PWM

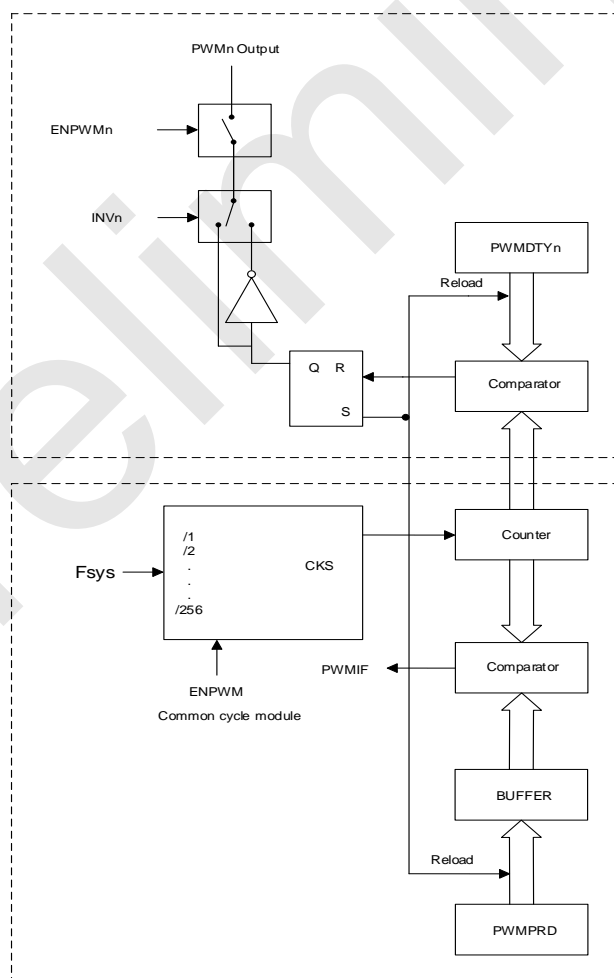

The SC92F742X provides an independent counter, which is able to support 6-channel PWM output: PWM0 ~ 5.

The SC92F742X PWM has the following functions:

- ① 8-bit precision;
- ② PWM0 ~ 5 shared the same clock cycle, but the duty cycle of each PWM channel can be configured separately
- ③ Output can be configured in forward or reverse direction;
- ④ Provide one PWM overflow interrupt.

The cycle and duty cycle of the SC92F742X PWM is adjustable. Register PWMCON controls the related setting of PWM0 ~ 5 status and PWMCFG0, PWMCFG1 sets the common cycle of PWM, and PWMDTY0 ~ 5 respectively control the duty of PWM0 ~ 5.

### 12.1 PWM block Diagram

PWMPRD[7:0] is a sharing cycle setting controller for six-channel PWM. Once the PWM counter counting to the preset value of PWMPRD[7:0], the counter will hop to 00h when the next PWM CLK comes, that is to say, the

cycle of PWM0~5 is  $(PWMPRD[7:0] + 1) \times \text{PWM clock}$ .

The counting time of PWM counter can be controlled by PWMCKS[2:0]. Different number of system clocks can be selected to count one unit (pre-scalar selector), that is select the divider ratio of PWM counter clock source to system clock  $f_{SYS}$ . PWM0 ~ 5 can also be used by PWMCFG INV0~INV2 to select whether or not the PWM output is reversed.

PWMPRD (D3H) PWM Period Configuration Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0

Bit Number	Bit Symbol	Description
7 ~ 0	PDT4[7: 0]	PWM4 duty cycle length configuration; High level width of PWM4 is (PDT4[7: 0]) PWM clocks.

PWMDTY5 (DFH) PWM5 Duty Cycle Configuration Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	PDT5[7: 0]							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
POR	0	0	0	0	0	0	0	0

Bit Number	Bit Symbol	Description
7 ~ 0	PDT5[7: 0]	PWM5 duty cycle length configuration; High level width of PWM5 is (PDT5[7: 0]) PWM clocks.

**IE1 (A9H) Interrupt Enable Register (Read/Write)**

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	-	-	-	-	EINT2	EBTM	EPWM	ESSI1
R/W	-	-	-	-	R/W	R/W	R/W	R/W
POR	x	x	x	x	0	0	0	0

Bit Number	Bit Symbol	Description
1	EPWM	PWM Interrupt Control Bit 0: Clear to disable the PWM interrupt 1: Set to enable the interrupt when PWM counter overflows

**IP1 (B9H) Interrupt Priority Register 1 (Read/Write)**

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	-	-	-	-	IPINT2	IPBTM	IPPWM	IPSSI1
R/W	-	-	-	-	R/W	R/W	R/W	R/W
POR	x	x	x	x	0	0	0	0

Bit Number	Bit Symbol	Description
1	IPPWM	PWM interrupt priority selection bit  0: Clear to configure PWM interrupt priority as “low”  1: Set to configure PWM interrupt priority as “ high”

**Notes:**

1. ENPWM bit can control whether PWM module works or not.
2. ENPWMn bit can select PWMn port as GPIO or PWMn output.
3. EPWM(IE1.1) bit can control whether or not PWM is allowed to generate interrupts.
4. If ENPWM sets as 1, the PWM module is turn on and ENPWMn=0, the PWM output is closed and acts as GPIO. At this time, PWM module can be used as an 8-bit Timer and EPWM(IE1.1) is set as 1 and PWM still produces interrupt.
5. Six PWM sharing cycles, and the PWM interrupt generated when overflow is the same interrupt vector.

## 12.3 PWM Waveform and Directions

The influence of changing various SFR parameters on PWM waveform is shown as follows:

### ① Diagram for Duty Cycle Change features

When PWMn outputs waveform, if it is required to change the duty cycle, users can change the value of high level configuration registers (PWMDTYn). Note that changing the value of PWMDTYn will change the duty cycle immediately.

### ② Period Change features

Diagram for Period Change Features

When PWMn outputs waveform, if it is required to change the period, the user can change the value of period configuration registers PWMPRD. Same as changing the duty cycle, change the value of PWMPRD will change the period immediately..

### ③ Relationship between Period and Duty cycle

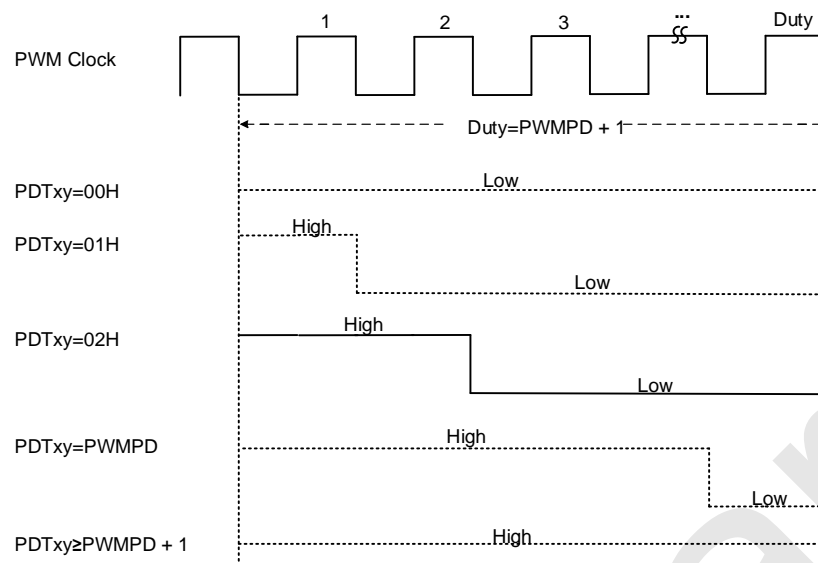

Diagram for Relationship between Period and Duty cycle

The relationship between period and duty cycle is shown in the figure above.

## 13 GP I/O

The SC92F742X offers up to 26 bidirectional controllable GPIOs, input and output control registers are used to control the input and output state of various ports, when the port is used as input, each I/O port is equipped with internal pull-up resistor controlled by PxPHY. Such 26 IOs are shared with other functions, including P0.0 ~ P0.4 can be used as LCD COM driver by configuring output voltage as  $1/2 V_{DD}$ . Under input or output state, what I/O port read from the value of port data register is the actual state value of the port.

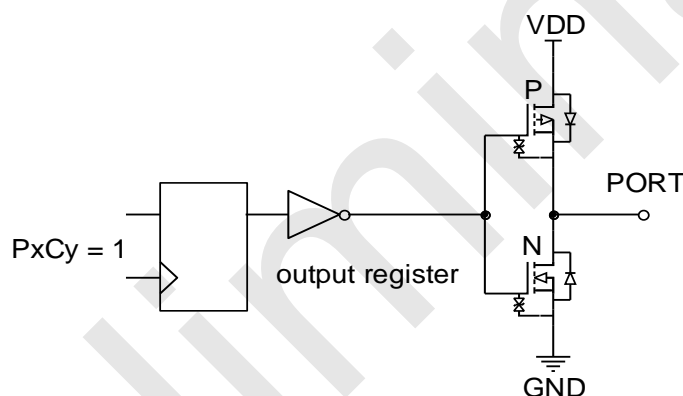

Note: Unused IO port or IO port with no package pin shall be configured as strong push-pull output mode.

### 13.1 GPIO Structure Diagram

#### Strong Push-pull Output Mode

In strong push-pull output mode, it is able to provide continuous high current drive: high output for the current larger than 20mA and low output for the current larger than 75mA

The port structure diagram for strong push-pull output mode is shown below:

Strong Push-pull Output Mode

#### Pull-up Input Mode

In pull-up input mode, a pull-up resistor is connected on the input port, only when the level on the input port is pulled down, low level signal can be detected.

The port structure diagram for pull-up input mode is shown below:

Pull-up Input Mode

#### High Impedance Input Mode. (Input only)

The port structure diagram for input only mode is shown below:

## 15 SPI/TWI/UART SERIAL INTERFACE SSI0, SSI1

The SC92F742X integrates two SPI/TWI/UART serial interface circuits (SSI), which is convenient for connecting MCU to devices or equipment with different interfaces. The user can configure SSI in any communication mode among SPI, TWI and UART by configuring SSMODn[1: 0] bit of register OTCON. Its features are shown below:

1. SPI mode can be configured as master mode or slave mode
2. TWI mode can only be used as slave in communication
3. UART mode can work in Mode 1 (10-bit full-duplex asynchronous communication) and Mode 3 (11-bit full-duplex asynchronous communication)

Specific configuration modes are shown below:

OTCON (8FH) Output Control Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Mnemonic	SSMOD[1: 0]		SSMOD0[1:0]		VOIRS[1: 0]		-	-
R/W	R/W	R/W	R/W	R/W	R/W	R/W	-	-
POR	0	0	0	0	0	0	x	x

Bit Number	Bit Mnemonic	Description
7 ~ 6	SSMOD1[1: 0]	SSI1 communication mode control bits  00: SSI1 OFF  01: SSI1 is set in SPI communication mode;

		10: SSI1 is set in TWI communication mode; 11: SSI1 is set in UART communication mode;
5 ~ 4	SSMOD0[1: 0]	SSI0 communication mode control bits  00: SSI0 OFF  01: SSI0 is set in SPI communication mode;  10: SSI0 is set in TWI communication mode;  11: SSI0 is set in UART communication mode;

## 15.1 Serial Peripheral Interface (SPI)

SSMODn[1: 0] = 01, SSI is configured as SPI interface. Serial Peripheral Interface (SPI) is a kind of high-speed serial communication interface, allowing MCU and peripheral equipment (including other MCUs) to conduct full-duplex synchronous serial communication.

### 15.1.1 SPI OPERATION-RELATED REGISTERS

SS0CON0 (A5H) SPI0 Control Register (Read/Write)

SS1CON0 (9DH) SPI1 Control Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Mnemonic	SPEN	-	MSTR	CPOL	CPHA	SPR2	SPR1	SPR0

R/W	R/W	R/W	-	-	R/W	R/W	-	R/W
POR	0	0	x	x	0	0	x	0

Bit Number	Bit Mnemonic	Description
7	SPIF	SPI Data Transmit Flag Bit  0: Must be cleared by software  1: Data transmission completed and flag is set to 1 by hardware
6	WCOL	Write-in Conflict Flag Bit  0: Cleared by software, indicating write-in conflict is processed  1: Set to 1 by hardware, indicating one conflict is detected
3	TXE	Transmit Buffer Empty Flag Bit  0: Transmitting buffer not empty  1: Transmitting buffer empty, must be cleared by software
2	DORD	Transfer Direction Configuration Bit  0: Transmit MSB first  1: Transmit LSB first
0	TBIE	Transmitting Buffer Interrupt Enable Bit  0: Transmission interrupt not enable  1: Transmission interrupt enable, when SPIF=1, TBIE=1, it will generate SPI interrupt
5 ~ 4, 1	-	Reserved

SS0DAT (A7H) SPI0 Data Register (Read/Write)

SS1DAT (9FH) SPI1 Data Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Mnemonic	SPD[7: 0]							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
POR	0	0	0	0	0	0	0	0

Bit Number	Bit Mnemonic	Description
7 ~ 0	SPD[7: 0]	SPI Data Cache Register  Data written to SSDAT will be sent to the transmitting shift register.  Upon reading SSDAT, data from the receive shift register is received.

### 15.1.2 SIGNAL DESCRIPTION

Master-Out/Slave-In (MOSI):

This signal connects master device with one slave device. Data is serially transmitted from master device to slave device via MOSI, featuring master device output and slave device input.

Master-In and Slave-Out (MISO):

This signal connects slave device with master device. Data is serially transmitted from slave device to master device via MISO, featuring slave device output and master device input. When SPI is configured as slave device and is not selected, the MISO pin of slave device is in high-impedance state.

SPI Serial Clock (SCK):

SCK signal is used to control synchronous movement of input and output data on MOSI and MISO. Transmit one byte for every 8 clock periods. If no slave device is selected, SCK signal will be ignored from slave device.

### 15.1.3 OPERATING MODES

SPI can be configured as master mode or slave mode. The configuration and initialization of SPI module can be completed via setting SSCON0 register (SPI Control Register) and SSCON1 (SPI State Register). After completing configuration, data is transmitted by setting SSCON0, SSCON1 and SSDAT (SPI Data Register).

During SPI communication period, data is synchronically and serially moved in or out. Serial clock line (SCK) makes data movement and sampling on two serial data lines (MOSI and MISO) keep synchronous. If any slave device is not selected, it is unable to participate in activities on SPI line.

When SPI master device transmits data to slave device via MOSI, slave device sends data to master device via MISO as response, which realizes synchronous full-duplex transmission of data transmitting and receiving at the same clock. The transmit shift register and the receive shift register use the same special function address. Conducting write operations to SPI data register(SSDAT) will write data to the transmit shift register, and conducting read operations to SSDAT will obtain the data from the receive shift register.

The SPI interface of some devices will lead to SS pin (Slave Select, active-low). When communicating with the SC92F742X SPI, the SS pin from other devices on SPI bus shall be connected based on different communication modes. The following table lists the connection modes of the SS pin from other devices on SPI bus under different communication modes of the SC92F742X SPI:

SC92F742X SPI	Other Devices on SPI Bus	Mode	SS of Slave Device (Slave Device Select Pins )
Master Mode	Slave Mode	One Master One	Pull low

		Slave	
		One Master Multiple Slaves	The SC92F742X leads to multiple I/Os, which respectively connect to the SS pin of slave device. Before data transmission, the SS pin of slave device must be pulled low
Slave Mode	Master Mode	One Master One Slave	Pull high

### Master Mode

- Mode Startup:

Start of all data transmission on SPI bus is controlled by SPI master device. When MSTR bit in SCON0 register is set to 1, SPI operates in master mode, and only one master device can start the transmission.

- Transmitting:

In SPI master mode, write one byte of data to SPI data register SSDAT, the data will write to the transmit shift buffer. If any data already exists in the transmit shift register, one WCOL signal will be generated from master SPI to indicate writing is too fast. However, data in the transmit shift register will not be influenced and transmitting will not be interrupted as well. Besides, if the transmit shift register is empty, the master device will move the data in the transmit shift register to MOSI line serially according to SPI clock frequency on SCK. After transmission, SPIF bit in SCON1 register will be set to 1. If SPI interrupt is allowed, when SPIF bit is set to 1, an interrupt will be generated as well.

- Receiving:

When master device transmits data to slave device via MOSI line, corresponding slave device will also transmit the contents in the transmit shift register to the receive shift register of master device via MISO line so as to realize full-duplex operations. Therefore, setting SPIF flag bit to 1 indicates that transmission is completed and data has been received. Data received from slave device is stored in the receive shift register of master device in accordance with MSB first or LSB first transmission direction. When one byte of data is completely moved to the receive register, the processor can obtain such data by reading SSDAT register.

### Slave Mode

- Mode Startup:

When the MSTR bit in SCON0 register is clear to 0, SPI operates in slave mode.

- Transmitting and Receiving:

In slave mode, according to SCK signal controlled by master device, data is moved in via MOSI pin and out via MISO pin. A 1-bit counter records the number of SCK edge. When the receive shift register moves in 8-bit data (one byte) and the transmit shift register moves out 8-bit data (one byte), SPIF flag is set to 1. Data can be obtained by reading SSDAT register. If SPI interrupt is allowed, when setting SPIF to 1, an interrupt will be generated as well. At this time, the receive shift register keeps original data and set SPIF bit to 1, thus SPI slave device will not receive any data until SPIF is cleared to 0. SPI slave device must write the data to be transmitted before master device starts a new data transmission to the transmit shift register. If no data is written before transmitting, slave device will transmit "0x00" bytes to master device. If SSDAT writing operation occurs during the process of transmission, the WCOL flag bit of SPI slave device is set to 1. That is to say, if data is already included in the transmit shift register, WCOL bit of SPI slave device is set to 1, indicating conflict of SSDAT writing. But the data of shift register will not be influenced and transmission will

not be interrupted.

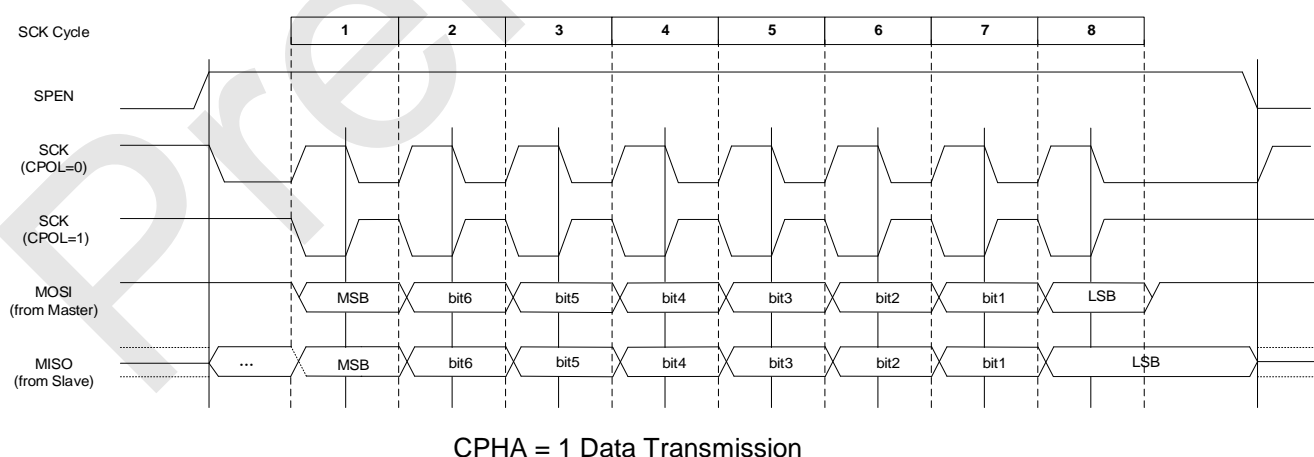

### 15.1.4 TRANSFER FORM

By setting CPOL bit and CPHA bit of SSCON0 register by software, the user can select four combinations of SPI clock polarity and clock phase. CPOL bit defines the polarity of clock, meaning the level status when idle, which has little influence on SPI transmission format. CPHA bit defines the phase of clock, meaning clock edge allowing data sampling shift. In two devices of master and slave communication, the configuration of clock polarity and phase shall be consistent.

When CPHA = 0, first edge of SCK captures data, and slave device must get the data ready before the first edge of SCK.

When CPHA = 1, master device outputs data to MOSI line at the first edge of SCK, slave device takes the first edge of SCK as the signal of start transmitting and start capturing data at the second edge of SCK. Therefore, user must complete SSDAT writing operation in two edges of first SCK. Such data transmission form is the preferred form of communication between one master device and one slave device.

### 15.1.5 ERROR DETECTION

Writing to SSDAT register may cause conflict during the period of transmitting data sequence, set WCOL bit in SSCON1 register to 1. Setting WCOL bit to 1 will not generate interrupt, and transmitting will not be interrupted. WCOL bit shall be cleared by software.

## 15.2 Two-Wire Interface (TWI)

SSMODn[1: 0] = 10, SSI is configured as TWI interface. The SC92F742X can only be used as slave device in TWI communication.

SS0CON0 (A5H) TWI0 Control Register (Read/Write)

SS1CON0 (9DH) TWI1 Control Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0

## 15.2.1 SIGNAL DESCRIPTION

### TWI Clock Signal Line (SCL)

This clock signal is sent from master device and connects all slave device. One byte of data is transmitted for every 9 clock periods. First 8 periods are used for data transmission and last one for receiver response clock.

### TWI Data Signal Line (SDA)

SDA is a bidirectional signal line, and shall be in high level when idling, which is pulled up by pull-up resistance on SDA line.

## 15.2.2 OPERATING MODES

TWI communication of the SC92F742X has only slave device mode:

- Mode Startup:

When TWI enabling flag bit opens (TWEN = 1) and receives start-up signal sent from master device, this mode is initiated.

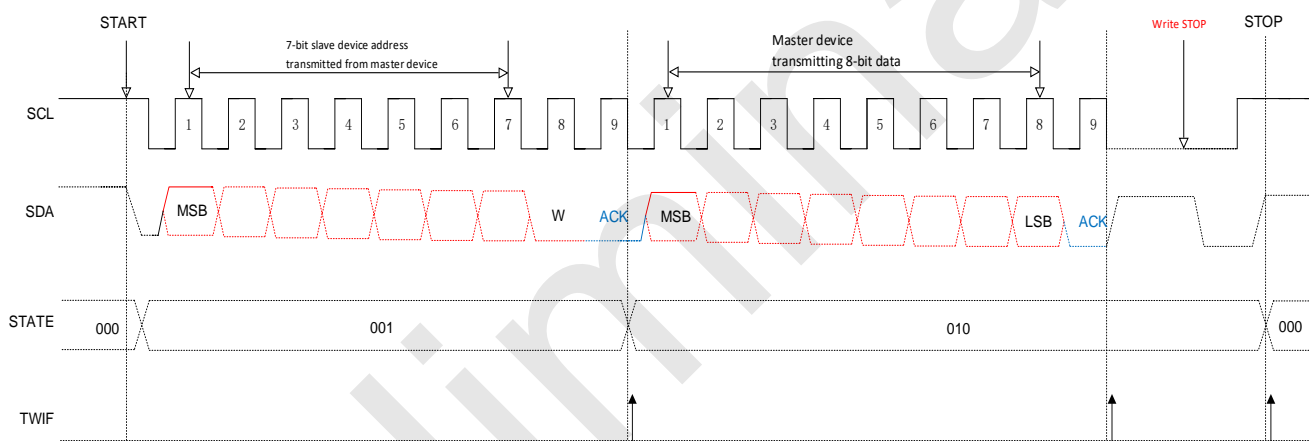

The slave device enters first frame address (STATE[2: 0] = 001) state from idle mode (STATE[2: 0] = 000), and waits for first frame data from master device. First frame data is sent by master device, including 7-bit address bit and 1-bit read and write bit, all slave devices on TWI bus will receive first frame data of master device. After transmitting first frame data, master device will release SDA signal line. If the address sent by master device is the same as the value of address register of slave device, it indicates that the slave device has been selected and the selected slave device will judge to connect the 8<sup>th</sup> bit on the bus, which is the data read and write bit (=1, reading the command; =0, writing the command), then occupies SDA signal line, after transmitting a low-level response signal at the 9<sup>th</sup> clock period of SCL, release the bus. After the slave device

is selected, enter into different status according to different read and write bits:

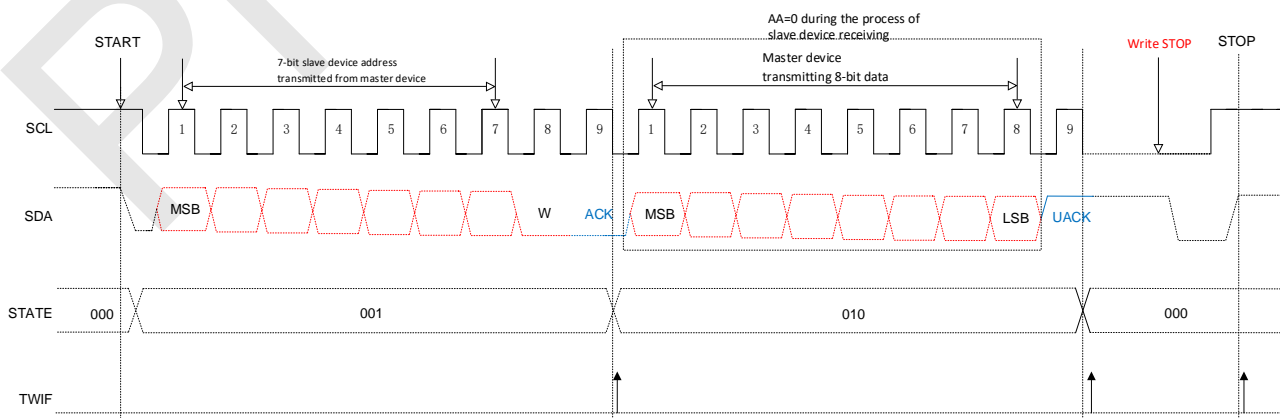

- Non-general address response, slave device receiving mode:

If the read and write bit received from the first frame is writing (0), the slave device enters into the receiving state of slave device (STATE [2: 0] = 010), and wait for data sent from receiving master device. Master device will release the bus for transmitting every 8 bits and then wait for the response signal of 9<sup>th</sup> period of slave device.

1. If the response signal from slave device is in low level, there are three modes of master communication:
  - 1) Continue to send data;
  - 2) Resend start signal, then the slave device enters into the state of receiving first frame address (STATE[2: 0] = 001);
  - 3) Send stopping signal, indicating this transmission is ended, slave device returns to idle state and wait for next start signal from master device.

2. If the response state of slave device is in high level (during the receiving process, the value of AA in slave device register is rewritten to 0), it indicates that after transmitting current bytes, the slave device will stop this transmission automatically and return to idle state (STATE[2: 0] = 000), without receiving data sent from master device any more.

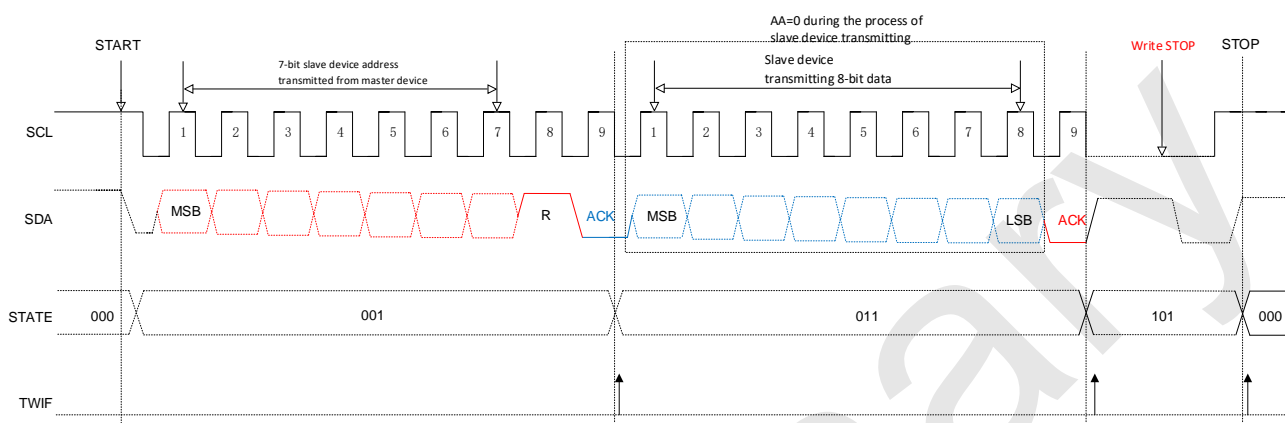

- Non-general address response, master device transmitting mode:

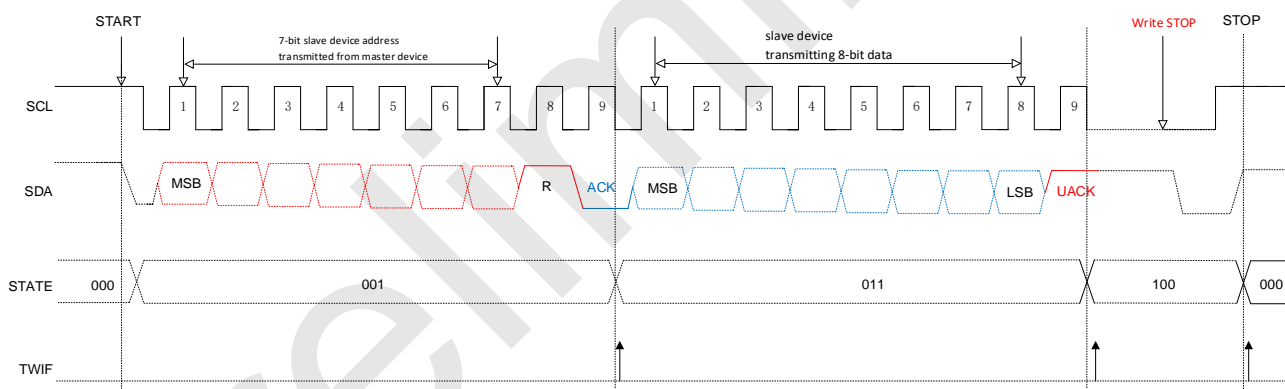

If the read and write bit received from the first frame is reading (1), the slave device will occupy the bus and

send data to master device. The slave device will release the bus for transmitting every 8-bit data and wait for the response from master device:

1. If the response from master device is low level, the slave device continues to send data. During the transmitting process, if the value of AA in slave device register is rewritten to 0, the slave device will automatically end the transmission and release the bus after transmitting current bytes, and wait for stop signal or restart signal of the master device (STATE[2: 0] = 101).

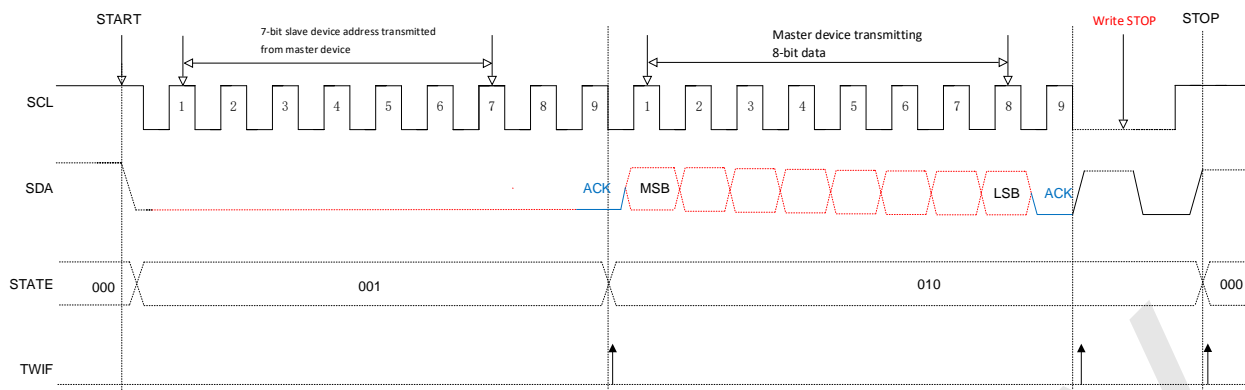

2. If the response from master device is high level, then the slave device state will wait for the stop signal or restart signal of the master device (STATE[2: 0] = 100).

### ● Response to General Address:

When GC=1, general address is allowed to be used. When the slave device enters into the state of receiving first frame address (STATE[2: 0] = 001), the address bit data received in first frame data will be 0x00, at this time, all slave device will respond the master device. The read and write bit sent from master device must be write (0), all slave device will enter into the state of receiving data (STATE[2: 0] = 010). The master device will release SDA line for transmitting every 8-bit data and read the state on SDA line:

1. If any response from slave device occurs, there are three modes of master device communication, as shown below:
  - 1) Continue to transmit data;
  - 2) Restart;
  - 3) Transmit the stop signal and end this communication.

2. If there is no response from slave device, SDA will be in idle state.

Note: When using general address under the mode of one master and multiple slaves, the read and write bit sent by master device can not be read (1) status, or else, all the other devices on the bus will also transmit response except for equipment transmitting data.

### 15.2.3 OPERATING STEPS

The operating steps of TWI in SSI are shown below:

- ① Configure SSMODn[1: 0] (n=0,1) and select TWI mode;
- ② Configure SSnCON0 TWI control register;
- ③ Configure SSnCON1 TWI address register;
- ④ If the slave device receives data, wait for interrupt flag bit TWIF in SSnCON0 to be set. The interrupt flag bit will be set to 1 when the slave device receives every 8-bit data. The interrupt flag bit shall be cleared by the user manually;
- ⑤ If the slave device transmits data, write the data to be transmit into TWDAT, TWI will transmit the data automatically. Interrupt flag bit TWIF will be set to 1 for transmitting every 8 bits.

## 15.3 Serial Interface (UART)

SSMOD[1: 0] = 11, SSI is configured as UART interface.

SS0CON0 (A5H) UART0 Control Register (Read/Write)

SS1CON0 (9DH) UART1 Control Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0

POR	0	0	0	0	0	0	0	0

Bit Number	Bit Mnemonic	Description
7 ~ 0	SBUF[7: 0]	Serial Data Buffer  SBUF contains two registers: one for transmit shift register and one for receiving latch, data writing to SBUF will be sent to shift register and

		initiate transmitting process, reading SBUF1 will return the contents of receiving latch.
--	--	---

## 16 ANALOG-TO-DIGITAL CONVERTER (ADC)

The SC92F742X has a 12-bit high-precision successive approximation ADC with 11-channel, the ADC channel is multiplexing with other IO ports. Cooperating with the internal 2.4V reference voltage, one internal channel connected to 1/4  $V_{DD}$  can be used for measuring  $V_{DD}$  voltage.

There are 2 options for ADC reference voltage:

- ①  $V_{DD}$  pin (internal  $V_{DD}$ );
- ② Precise 2.4V reference output from internal Regulator.

### 16.1 ADC-related Registers

ADCCON (ADH) ADC Control Register (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Symbol	ADCEN	ADCS	LOWSP	EOC/ADCIF	ADCIS[3: 0]			
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
POR	0	0	0	0	0	0	0	n

Bit Number	Bit Symbol	Description
7	ADCEN	ADC Power Control Bit  0: Disable ADC module power  1: Enable ADC module power
6	ADCS	ADC Start Trigger Control Bit (ADC Start)  Write "1" for this bit, an ADC conversion started, this bit is the trigger signal only for ADC switch. This bit is valid only for writing "1".  Note: After writing "1" to ADCS, do not write to the ADCCON register until the interrupt flag EOC/ADCIF is set.
5	LOWSP	ADC Sampling Clocks Selector:

		<p>0: Set the clock frequency as 2MHz for ADC</p> <p>1: Set the clock frequency as 333kHz for ADC</p> <p>LOWSP controls ADC sampling clock frequency, conversion clock frequency of ADC is fixed at 2MHz, independent of the influence of LOWSP bit</p> <p>The whole process from sampling to conversion of ADC needs 6 ADC sampling clocks plus 14 ADC conversion clocks, therefore, in practical application, the total time of ADC from sampling to conversion shall be calculated as follows:</p> <p>LOWSP=0: <math>TADC1=6*(1/2MHz)+14*(1/2\text{ MHz})=10\mu s</math> ;</p> <p>LOWSP=1: <math>TADC2=6*(1/333kHz)+14*(1/2\text{ MHz})=25\mu s</math> .`</p>
5	EOC /ADCIF	<p>End Of Conversion / ADC Interrupt Flag</p> <p>0: Conversion not completed</p> <p>1: ADC conversion completed and need the user cleared up by software.</p> <p>ADC conversion completion flag EOC: when the user sets up ADCS for conversions, this bit will be cleared to 0 by hardware automatically; after completing conversion, this bit will be configured to 1 automatically by hardware;</p> <p>ADC interrupt request flag ADCIF: this bit is also used as interrupt request flag of ADC interrupt. If ADC interrupt is enabled, this bit must be cleared by the user with software after ADC interrupt generated.</p>
4 ~ 0	ADCIS[4: 0]	<p>ADC Input Selection Bits</p> <p>0000: Select AIN0 as ADC input</p> <p>0001: Select AIN1 as ADC input</p> <p>0010: Select AIN2 as ADC input</p> <p>0011: Select AIN3 as ADC input</p> <p>0100: Select AIN4 as ADC input</p> <p>0101: Select AIN5 as ADC input</p> <p>0110: Select AIN6 as ADC input</p> <p>0111: Select AIN7 as ADC input</p> <p>1000: Select AIN8 as ADC input</p> <p>1001: Select AIN9 as ADC input</p> <p>1010 ~ 1110: Reserved</p> <p>1111: ADC input is 1/4 VDD, used for measuring power voltage</p>

## 16.2 ADC Conversion Steps

Operating steps for the user to practically conduct ADC conversion are shown below:

- ① Configure ADC input pin; (configure corresponding bit of AINx as ADC input, in general, ADC pin will be prefixed);
- ② Configure ADC reference voltage Vref and ADC conversion frequency;
- ③ Enable ADC;
- ④ Select ADC input channel; (Configure ADCIS bit and select ADC input channel);
- ⑤ Enable ADCS, and start conversion;
- ⑥ Wait for EOC/ADCIF=1, if ADC interrupt is enabled, ADC interrupt will be generated and the user shall clear EOC/ADCIF flag to 0 by software;
- ⑦ Obtain 12-bit data from ADCVH, ADCVL from high bit to low bit, and complete a conversion
- ⑧ If no change in input channel, repeat Step 5 to Step 7 for next conversion.

Note: Before setting up IE[6] (EADC), it is recommended for the user to use software to clear the EOC/ADCIF flag first. After completing ADC interrupt service process, user shall eliminate EOC/ADCIF to avoid generating ADC interrupt constantly.

## 17 EEPROM AND IAP OPERATIONS

EEPROM and IAP operating modes are shown below:

1. 128 bytes EEPROM can be used as data storage;
2. The Code area of IC and 128 bytes of EEPROM can be used for IAP operations, which is mainly used for remote program updating.

As Code Option, the user shall select EEPROM and IAP operating space before it is written to IC by programmer:

OP\_CTM1 (C2H@FFH) Customer Option Register 1 (Read/Write)

POR	x	x	x	x	0	0	0	0

Bit Number	Bit symbol	Description
3 ~ 2	PAYTIMES[1: 0]	<p>Upon EEPROM/IAP writing operation, CPU Hold Time length configuration</p> <p>00: Configure CPU HOLD TIME 6mS@16/8/4/1.33 MHz</p> <p>01: Configure CPU HOLD TIME 3mS@16/8/4/1.33 MHz</p> <p>10: Configure CPU HOLD TIME 1.5mS@16/8/4/1.33 MHz</p> <p>11: Reserved</p> <p>Notes: The CPU Hold is for PC pointer, other functional module continues to work; interrupt flag is saved, and interrupt is generated after completing Hold, but several times of interrupt can only be saved once.</p> <p>Recommended Selection: 2.7V ~ 5.5 V for V<sub>DD</sub>, 10 is available</p> <p>2.4V ~ 5.5V for V<sub>DD</sub>, 01 or 00 is available</p>
1 ~ 0	CMD[1: 0]	<p>EEPROM / IAP writing operating command</p> <p>10: Write</p> <p>Other: Reserved</p> <p>Note: The statement of EEPROM/IAP write operation shall be followed by at least 8 NOP instructions to guarantee subsequent instruction can be implemented normally after finishing IAP operation!</p>

## 17.2 EEPROM / IAP Operating Procedures:

Writing procedure of the SC92F742X EEPROM/IAP are shown below:

- ① Write 0x00 into IAPADE[7: 0]: select Code Area and conduct IAP operation; write 0x02 into IAPADE[7: 0]: select EEPROM and conduct EEPROM reading and writing operations;
- ② Write data into IAPDAT[7: 0] (data for EEPROM / IAP writing ready);
- ③ Write address into {IAPADR[13:8], IAPADR[7: 0]} (target address of EEPROM/IAP operation ready);
- ④ Write a nonzero value n into IAPKEY[7: 0] (switch on protection of EEPROM / IAP, and EEPROM / IAP function will be switched off when there is no writing command within n system clocks);
- ⑤ Write CPU Hold time into IAPCTL[3: 0] (configure CPU Hold time by setting CMD[1: 0] to 1 or 0, CPU is Hold up and start up EEPROM/IAP writing);
- ⑥ EEPROM/IAP writing ends, CPU proceeds to subsequent operations.

Notes:

1. When programming IC, if "Code Area Prohibits IAP Operations" is selected by Code Option, IAP is unavailable upon IAPADE[7: 0]=0x00 (Select Code Area), meaning it is unable to write data, and such

data can only be read by MOVC command.

2. When IAPADE=0x01 or 0x02, MOVC instruction and writing operation are conducted in EEPROM or IFB area. If any interrupt occurs and there are also MOVC operations in this interrupt, it may result in error of MOVC operations and thus abnormal operation of program. To avoid such situation, the user shall disable global interrupt control bit (EA=0) before conducting IAPADE=0x01 or 0x02 operations. After operation completed, configure IAPADE =0x00 and enable global interrupt control bit (EA=1).

### 17.2.1 128 BYTES INDEPENDENT EEPROM OPERATING DEMO PROGRAMME

```
#include "intrins.h"
```

```
unsigned char EE_Add;
```

```
unsigned char EE_Data;
```

```
unsigned char code * POINT =0x0000;
```

C Demo Program of EEPROM Write Operation:

```
EA = 0;                // Disable global Interrupt

IAPADE = 0x02;          //Select EEPROM Area

IAPDAT = EE_Data;       //Transmit data to EEPROM data register

IAPADH = 0x00;          //High-bit address default write 0x00

IAPADL = EE_Add;        //Write EEPROM target address low bit

IAPKEY = 0xF0;          //This value can be adjusted as required: it shall guarantee that

                        // The time interval between this instruction implemented and writing
                        // IAPCTL value shall be less than 240 (0xf0) system clocks, or else, IAP function
                        // is closed;

                        //Pay special attention to enabling interrupt;

IAPCTL = 0x0A;          //Implement EEPROM write operation, 1.5ms@16/8/4/1.33 MHz;

_nop_ ();              //Wait (at least 8 _nop_ ())

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

IAPADE = 0x00;          //Return to ROM Area

EA = 1;                //Enable master interrupt
```

C Demo Program of EEPROM Read Operation

```
EA = 0;                //Disable master interrupt

IAPADE = 0x02;          //Select EEPROM Area

EE_Data = * ( POINT +EE_Add);    //Read value in IAP_Add to IAP_Data

IAPADE = 0x00;          //Return to ROM Area , prevent MOVC operates to EEPROM

EA = 1;                // Enable global interrupt
```

## 17.2.2 CODE MEMORY IAP OPERATING DEMO PROGRAMME

```
#include "intrins.h"

unsigned int IAP_Add;

unsigned char IAP_Data;

unsigned char code * POINT =0x0000;
```

C Demo Program of IAP Write Operation:

```
IAPADE = 0x00;          //Select Code Area

IAPDAT = IAP_Data;      //Transmit data to IAP data register

IAPADH = (unsigned char) ( IAP_Add >> 8);    //Write IAP target address high bit

IAPADL = (unsigned char)IAP_Add;              //Write IAP target address low bit

IAPKEY = 0xF0;          //This value can be adjusted as required; it shall guarantee this
                        //instruction is implemented to assigned IAPTL value;

                        // Time interval shall be less than 240 (0xf0) system clocks, or
                        // else, IAP function is closed;

                        //Pay special attention upon starting interrupt

IAPCTL = 0x0A;          //Implement EEPROM write operation, 1.5ms@16/8/4/1.33MHz;

_nop_ ();              //Wait (at least 8 _nop_ ())

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();

_nop_ ();
```

```
_nop_ ();
```

C Demo Program of IAP Read Operation:

```
IAPADE = 0x00;           //Select Code Area

IAP_Data = * ( POINT+IAP_Add); //Read value in IAP_Add to IAP_Data
```

Note: IAP operation has certain risks, the user shall implement corresponding safety measures in software. Misoperation may result in the user programme to be rewritten! Unless such function is required by the user (such as used for remote programme update, etc.), it is not recommended to be used by the user.

## 18 CHECKSUM MODULE

The SC92F742X is equipped with a check sum module, which is used for generating 16-bit check sum of code memory in real time. The user can compare such check sum with theoretical value to monitor whether the contents in code memory are correct.

Note: Check sum is the sum of data in the whole code memory, which is the data of 0000H ~ 3FFDH address unit. If there are residual values from the user's last operations in address unit, it may result in inconsistency of check sum with theoretical value. Therefore, it is recommended that the user shall erase the whole Code memory or write 0 before programming code so as to guarantee the consistency between check sum and theoretical value.

### 18.1 CheckSum-Related Registers

CHKSUML (FCH) Check Sum Result Register Low Bit (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
Bit Mnemonic	CHKSUML[7: 0]							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
POR	0	0	0	0	0	0	0	0

Bit Number	Bit Mnemonic	Description
7 ~ 0	CHKSUML [7: 0]	CheckSum Result Register Low Bit

CHKSUMH (FDH) Check Sum Result Register High Bit (Read/Write)

Bit Number	7	6	5	4	3	2	1	0
------------	---	---	---	---	---	---	---	---

Bit Mnemonic	CHKSUMH[7: 0]							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
POR	0	0	0	0	0	0	0	0

Bit Number	Bit Mnemonic	Description
7 ~ 0	CHKSUMH [7: 0]	CheckSum Result Register High Bit

**OPERCON (EFH) Arithmetic Control Register (Read/Write)**

Bit Number	7	6	5	4	3	2	1	0
Bit Mnemonic	-	-	-	-	-	-	-	CHKSUMS
R/W	-	-	-	-	-	-	-	R/W
POR	x	x	x	x	x	x	x	0

Bit Number	Bit Mnemonic	Description
0	CHKSUMS	<p>CheckSum Operation Starts Trigger Control Bit (Start)</p> <p>Write "1" for this bit, start to conduct Check sum calculation. This bit is valid for only writing 1.</p>

## 19 ELECTRICAL CHARACTERISTICS

### 19.1 absolute maximum ratings

Symbol	Parameter	Min Value	Max Value	Unit
V <sub>DD</sub> /V <sub>SS</sub>	DC supply voltage	-0.3	5.5	V
Voltage ON any Pin	Input / Output voltage of any pin	-0.3	V <sub>DD</sub> +0.3	V
T <sub>A</sub>	Ambient temperature	-40	85	°C
T <sub>STG</sub>	Storage temperature	-55	125	°C

### 19.2 Recommended Operating Conditions

Symbol	Parameter	Min Value	Max Value	Unit	System Clock Frequency
V <sub>DD1</sub>	Operating voltage	2.9	5.5	V	16MHz
V <sub>DD2</sub>	Operating voltage	2.4	5.5	V	8/4/1.33MHz
T <sub>A</sub>	Ambient temperature	-40	85	°C	-

### 19.3 D.C. Characteristics

(V<sub>DD</sub> = 5V, T<sub>A</sub> = +25°C, unless otherwise specified)

Symbol	Parameter	Min Value	Typical Value	Max Value	Unit	Testing Conditions
Current						
I <sub>op1</sub>	Operating current	-	8.0	-	mA	f <sub>sys</sub> =16MHz
I <sub>op2</sub>	Operating current	-	5.8	-	mA	f <sub>sys</sub> =8MHz

I <sub>op3</sub>	Operating current	-	4.7	-	mA	f <sub>sys</sub> =4MHz
I <sub>op4</sub>	Operating current	-	4.0	-	mA	f <sub>sys</sub> =1.33MHz
I <sub>pd1</sub>	Standby Current (Power Down Mode)	-	0.7	1.0	μA	
I <sub>IDL1</sub>	Standby Current (IDLE Mode)	-	7	-	mA	
I <sub>BTM</sub>	Base Timer Operating Current	-	7	10	μA	BTMFS[2: 0]= 111  One interrupt occurs for every 2.0 seconds
I <sub>WDT</sub>	WDT Current	-	6	10	μA	WDTCKS[2: 0]= 000  WDT overflows every 500ms
I/O Port Features
